About This Book

The MIPS32® Instruction Set Manual comes as part of a multi-volume set.

- Volume I-A describes conventions used throughout the document set, and provides an introduction to the MIPS32® Architecture
- Volume I-B describes conventions used throughout the document set, and provides an introduction to the microMIPS™ Architecture
- Volume II-A provides detailed descriptions of each instruction in the MIPS32® instruction set
- Volume II-B provides detailed descriptions of each instruction in the microMIPS32™ instruction set
- Volume III describes the MIPS32® and microMIPS32™ Privileged Resource Architecture which defines and governs the behavior of the privileged resources included in a MIPS® processor implementation
- Volume IV-a describes the MIPS16e™ Application-Specific Extension to the MIPS32® Architecture. Beginning with Release 3 of the Architecture, microMIPS is the preferred solution for smaller code size. Release 6 removes MIPS16e: MIPS16e cannot be implemented with Release 6.
- Volume IV-b describes the MDMX™ Application-Specific Extension to the MIPS64® Architecture and microMIPS64™. It is not applicable to the MIPS32® document set nor the microMIPS32™ document set. With Release 5 of the Architecture, MDMX is deprecated. MDMX and MSA can not be implemented at the same time. Release 6 removes MDMX: MDMX cannot be implemented with Release 6.
- Volume IV-c describes the MIPS-3D® Application-Specific Extension to the MIPS® Architecture. Release 6 removes MIPS-3D: MIPS-3D cannot be implemented with Release 6.
- Volume IV-d describes the SmartMIPS® Application-Specific Extension to the MIPS32® Architecture and the microMIPS32™ Architecture. Release 6 removes SmartMIPS: SmartMIPS cannot be implemented with Release 6, neither MIPS32 Release 6 nor MIPS64 Release 6.
- Volume IV-e describes the MIPS® DSP Module to the MIPS® Architecture.
- Volume IV-f describes the MIPS® MT Module to the MIPS® Architecture
- Volume IV-h describes the MIPS® MCU Application-Specific Extension to the MIPS® Architecture
- Volume IV-i describes the MIPS® Virtualization Module to the MIPS® Architecture
- Volume IV-j describes the MIPS® SIMD Architecture Module to the MIPS® Architecture

1.1 Typographical Conventions

This section describes the use of *italic*, **bold** and `courier` fonts in this book.

1.1.1 Italic Text

- is used for *emphasis*
- is used for *bits*, *fields*, and *registers* that are important from a software perspective (for instance, address bits used by software, and programmable fields and registers), and various *floating point instruction formats*, such as *S* and *D*
- is used for the memory access types, such as *cached* and *uncached*

1.1.2 Bold Text

- represents a term that is being **defined**
- is used for **bits** and **fields** that are important from a hardware perspective (for instance, **register** bits, which are not programmable but accessible only to hardware)
- is used for ranges of numbers; the range is indicated by an ellipsis. For instance, **5..1** indicates numbers 5 through 1
- is used to emphasize **UNPREDICTABLE** and **UNDEFINED** behavior, as defined below.

1.1.3 Courier Text

`Courier` fixed-width font is used for text that is displayed on the screen, and for examples of code and instruction pseudocode.

1.2 UNPREDICTABLE and UNDEFINED

The terms **UNPREDICTABLE** and **UNDEFINED** are used throughout this book to describe the behavior of the processor in certain cases. **UNDEFINED** behavior or operations can occur only as the result of executing instructions in a privileged mode (i.e., in Kernel Mode or Debug Mode, or with the CP0 usable bit set in the Status register). Unprivileged software can never cause **UNDEFINED** behavior or operations. Conversely, both privileged and unprivileged software can cause **UNPREDICTABLE** results or operations.

1.2.1 UNPREDICTABLE

UNPREDICTABLE results may vary from processor implementation to implementation, instruction to instruction, or as a function of time on the same implementation or instruction. Software can never depend on results that are **UNPREDICTABLE**. **UNPREDICTABLE** operations may cause a result to be generated or not. If a result is generated, it is **UNPREDICTABLE**. **UNPREDICTABLE** operations may cause arbitrary exceptions.

UNPREDICTABLE results or operations have several implementation restrictions:

- Implementations of operations generating **UNPREDICTABLE** results must not depend on any data source (memory or internal state) which is inaccessible in the current processor mode

- **UNPREDICTABLE** operations must not read, write, or modify the contents of memory or internal state which is inaccessible in the current processor mode. For example, **UNPREDICTABLE** operations executed in user mode must not access memory or internal state that is only accessible in Kernel Mode or Debug Mode or in another process
- **UNPREDICTABLE** operations must not halt or hang the processor

1.2.2 UNDEFINED

UNDEFINED operations or behavior may vary from processor implementation to implementation, instruction to instruction, or as a function of time on the same implementation or instruction. **UNDEFINED** operations or behavior may vary from nothing to creating an environment in which execution can no longer continue. **UNDEFINED** operations or behavior may cause data loss.

UNDEFINED operations or behavior has one implementation restriction:

- **UNDEFINED** operations or behavior must not cause the processor to hang (that is, enter a state from which there is no exit other than powering down the processor). The assertion of any of the reset signals must restore the processor to an operational state

1.2.3 UNSTABLE

UNSTABLE results or values may vary as a function of time on the same implementation or instruction. Unlike **UNPREDICTABLE** values, software may depend on the fact that a sampling of an **UNSTABLE** value results in a legal transient value that was correct at some point in time prior to the sampling.

UNSTABLE values have one implementation restriction:

- Implementations of operations generating **UNSTABLE** results must not depend on any data source (memory or internal state) which is inaccessible in the current processor mode

1.3 Special Symbols in Pseudocode Notation

In this book, algorithmic descriptions of an operation are described using a high-level language pseudocode resembling Pascal. Special symbols used in the pseudocode notation are listed in Table 1.1.

Table 1.1 Symbols Used in Instruction Operation Statements

Symbol	Meaning
\leftarrow	Assignment
$=, \neq$	Tests for equality and inequality
\parallel	Bit string concatenation
x^y	A y -bit string formed by y copies of the single-bit value x
$b\#n$	A constant value n in base b . For instance $10\#100$ represents the decimal value 100, $2\#100$ represents the binary value 100 (decimal 4), and $16\#100$ represents the hexadecimal value 100 (decimal 256). If the "b#" prefix is omitted, the default base is 10.
$0bn$	A constant value n in base 2. For instance $0b100$ represents the binary value 100 (decimal 4).
$0xn$	A constant value n in base 16. For instance $0x100$ represents the hexadecimal value 100 (decimal 256).

Table 1.1 Symbols Used in Instruction Operation Statements (Continued)

Symbol	Meaning
$x_{y..z}$	Selection of bits y through z of bit string x . Little-endian bit notation (rightmost bit is 0) is used. If y is less than z , this expression is an empty (zero length) bit string.
$x.\text{bit}[y]$	Bit y of bitstring x . Alternative to the traditional MIPS notation x_y .
$x.\text{bits}[y..z]$	Selection of bits y through z of bit string x . Alternative to the traditional MIPS notation $x_{y..z}$.
$x.\text{byte}[y]$	Byte y of bitstring x . Equivalent to the traditional MIPS notation $x_{8*y+7..8*y}$.
$x.\text{bytes}[y..z]$	Selection of bytes y through z of bit string x . Alternative to the traditional MIPS notation $x_{8*y+7..8*z}$.
$x.\text{halfword}[y]$ $x.\text{word}[i]$ $x.\text{doubleword}[i]$	Similar extraction of particular bitfields (used in e.g., MSA packed SIMD vectors).
$x.\text{bit}31$, $x.\text{byte}0$, etc.	Examples of abbreviated form of $x.\text{bit}[y]$, etc. notation, when y is a constant.
$x.\text{fiel}dy$	Selection of a named subfield of bitstring x , typically a register or instruction encoding. More formally described as “Field y of register x ”. For example, FIR.D = “the D bit of the Coprocessor 1 Floating-point Implementation Register (FIR)”.
$+$, $-$	2’s complement or floating point arithmetic: addition, subtraction
$*$, \times	2’s complement or floating point multiplication (both used for either)
div	2’s complement integer division
mod	2’s complement modulo
$/$	Floating point division
$<$	2’s complement less-than comparison
$>$	2’s complement greater-than comparison
\leq	2’s complement less-than or equal comparison
\geq	2’s complement greater-than or equal comparison
nor	Bitwise logical NOR
xor	Bitwise logical XOR
and	Bitwise logical AND
or	Bitwise logical OR
not	Bitwise inversion
$\&\&$	Logical (non-Bitwise) AND
\ll	Logical Shift left (shift in zeros at right-hand-side)
\gg	Logical Shift right (shift in zeros at left-hand-side)
GPRLEN	The length in bits (32 or 64) of the CPU general-purpose registers
$\text{GPR}[x]$	CPU general-purpose register x . The content of $\text{GPR}[0]$ is always zero. In Release 2 of the Architecture, $\text{GPR}[x]$ is a short-hand notation for $\text{SGPR}[\text{SRSCtl}_{\text{CSS}}, x]$.
$\text{SGPR}[s,x]$	In Release 2 of the Architecture and subsequent releases, multiple copies of the CPU general-purpose registers may be implemented. $\text{SGPR}[s,x]$ refers to GPR set s , register x .
$\text{FPR}[x]$	Floating Point operand register x
$\text{FCC}[CC]$	Floating Point condition code CC . $\text{FCC}[0]$ has the same value as $\text{COC}[1]$. Release 6 removes the floating point condition codes.
$\text{FPR}[x]$	Floating Point (Coprocessor unit 1), general register x

Table 1.1 Symbols Used in Instruction Operation Statements (Continued)

Symbol	Meaning
$CPR[z,x,s]$	Coprocessor unit z , general register x , select s
$CP2CPR[x]$	Coprocessor unit 2, general register x
$CCR[z,x]$	Coprocessor unit z , control register x
$CP2CCR[x]$	Coprocessor unit 2, control register x
$COC[z]$	Coprocessor unit z condition signal
$Xlat[x]$	Translation of the MIPS16e GPR number x into the corresponding 32-bit GPR number
BigEndianMem	Endian mode as configured at chip reset (0 → Little-Endian, 1 → Big-Endian). Specifies the endianness of the memory interface (see LoadMemory and StoreMemory pseudocode function descriptions) and the endianness of Kernel and Supervisor mode execution.
BigEndianCPU	The endianness for load and store instructions (0 → Little-Endian, 1 → Big-Endian). In User mode, this endianness may be switched by setting the <i>RE</i> bit in the <i>Status</i> register. Thus, BigEndianCPU may be computed as (BigEndianMem XOR ReverseEndian).
ReverseEndian	Signal to reverse the endianness of load and store instructions. This feature is available in User mode only, and is implemented by setting the <i>RE</i> bit of the <i>Status</i> register. Thus, ReverseEndian may be computed as (SR _{RE} and User mode).
<i>LLbit</i>	Bit of virtual state used to specify operation for instructions that provide atomic read-modify-write. <i>LLbit</i> is set when a linked load occurs and is tested by the conditional store. It is cleared, during other CPU operation, when a store to the location would no longer be atomic. In particular, it is cleared by exception return instructions.
I , I+n , I-n :	<p>This occurs as a prefix to <i>Operation</i> description lines and functions as a label. It indicates the instruction time during which the pseudocode appears to “execute.” Unless otherwise indicated, all effects of the current instruction appear to occur during the instruction time of the current instruction. No label is equivalent to a time label of I. Sometimes effects of an instruction appear to occur either earlier or later — that is, during the instruction time of another instruction. When this happens, the instruction operation is written in sections labeled with the instruction time, relative to the current instruction I, in which the effect of that pseudocode appears to occur. For example, an instruction may have a result that is not available until after the next instruction. Such an instruction has the portion of the instruction operation description that writes the result register in a section labeled I+1.</p> <p>The effect of pseudocode statements for the current instruction labeled I+1 appears to occur “at the same time” as the effect of pseudocode statements labeled I for the following instruction. Within one pseudocode sequence, the effects of the statements take place in order. However, between sequences of statements for different instructions that occur “at the same time,” there is no defined order. Programs must not depend on a particular order of evaluation between such sections.</p>
PC	<p>The <i>Program Counter</i> value. During the instruction time of an instruction, this is the address of the instruction word. The address of the instruction that occurs during the next instruction time is determined by assigning a value to <i>PC</i> during an instruction time. If no value is assigned to <i>PC</i> during an instruction time by any pseudocode statement, it is automatically incremented by either 2 (in the case of a 16-bit MIPS16e instruction) or 4 before the next instruction time. A taken branch assigns the target address to the <i>PC</i> during the instruction time of the instruction in the branch delay slot.</p> <p>In the MIPS Architecture, the <i>PC</i> value is only visible indirectly, such as when the processor stores the restart address into a GPR on a jump-and-link or branch-and-link instruction, or into a Coprocessor 0 register on an exception. Release 6 adds <i>PC</i>-relative address computation and load instructions. The <i>PC</i> value contains a full 32-bit address, all of which are significant during a memory reference.</p>

Table 1.1 Symbols Used in Instruction Operation Statements (Continued)

Symbol	Meaning						
ISA Mode	<p>In processors that implement the MIPS16e Application Specific Extension or the microMIPS base architectures, the <i>ISA Mode</i> is a single-bit register that determines in which mode the processor is executing, as follows:</p> <table data-bbox="597 394 1266 541"> <tr> <th>Encoding</th><th>Meaning</th></tr> <tr> <td>0</td><td>The processor is executing 32-bit MIPS instructions</td></tr> <tr> <td>1</td><td>The processor is executing MIPS16e or microMIPS instructions</td></tr> </table> <p>In the MIPS Architecture, the <i>ISA Mode</i> value is only visible indirectly, such as when the processor stores a combined value of the upper bits of PC and the <i>ISA Mode</i> into a GPR on a jump-and-link or branch-and-link instruction, or into a Coprocessor 0 register on an exception.</p>	Encoding	Meaning	0	The processor is executing 32-bit MIPS instructions	1	The processor is executing MIPS16e or microMIPS instructions
Encoding	Meaning						
0	The processor is executing 32-bit MIPS instructions						
1	The processor is executing MIPS16e or microMIPS instructions						
PABITS	The number of physical address bits implemented is represented by the symbol PABITS. As such, if 36 physical address bits were implemented, the size of the physical address space would be $2^{\text{PABITS}} = 2^{36}$ bytes.						
FP32RegistersMode	<p>Indicates whether the FPU has 32-bit or 64-bit floating point registers (FPRs). In MIPS32 Release 1, the FPU has 32, 32-bit FPRs, in which 64-bit data types are stored in even-odd pairs of FPRs. In MIPS64, (and optionally in MIPS32 Release2 and Release 3) the FPU has 32 64-bit FPRs in which 64-bit data types are stored in any FPR.</p> <p>In MIPS32 Release 1 implementations, FP32RegistersMode is always a 0. MIPS64 implementations have a compatibility mode in which the processor references the FPRs as if it were a MIPS32 implementation. In such a case FP32RegistersMode is computed from the FR bit in the <i>Status</i> register. If this bit is a 0, the processor operates as if it had 32, 32-bit FPRs. If this bit is a 1, the processor operates with 32 64-bit FPRs.</p> <p>The value of FP32RegistersMode is computed from the FR bit in the <i>Status</i> register.</p>						
InstructionInBranchDelaySlot	Indicates whether the instruction at the Program Counter address was executed in the delay slot of a branch or jump. This condition reflects the <i>dynamic</i> state of the instruction, not the <i>static</i> state. That is, the value is false if a branch or jump occurs to an instruction whose PC immediately follows a branch or jump, but which is not executed in the delay slot of a branch or jump.						
SignalException(exception, argument)	Causes an exception to be signaled, using the exception parameter as the type of exception and the argument parameter as an exception-specific argument). Control does not return from this pseudocode function—the exception is signaled at the point of the call.						

1.4 Notation for Register Field Accessibility

In this document, the read/write properties of register fields use the notations shown in Table 1.1.

Table 1.2 Read/Write Register Field Notation

Read/Write Notation	Hardware Interpretation	Software Interpretation
R/W	<p>A field in which all bits are readable and writable by software and, potentially, by hardware. Hardware updates of this field are visible by software read. Software updates of this field are visible by hardware read.</p> <p>If the Reset State of this field is “Undefined”, either software or hardware must initialize the value before the first read will return a predictable value. This should not be confused with the formal definition of UNDEFINED behavior.</p>	

Table 1.2 Read/Write Register Field Notation (Continued)

Read/Write Notation	Hardware Interpretation	Software Interpretation
R	<p>A field which is either static or is updated only by hardware.</p> <p>If the Reset State of this field is either “0”, “Preset”, or “Externally Set”, hardware initializes this field to zero or to the appropriate state, respectively, on powerup. The term “Preset” is used to suggest that the processor establishes the appropriate state, whereas the term “Externally Set” is used to suggest that the state is established via an external source (e.g., personality pins or initialization bit stream). These terms are suggestions only, and are not intended to act as a requirement on the implementation.</p> <p>If the Reset State of this field is “Undefined”, hardware updates this field only under those conditions specified in the description of the field.</p>	<p>A field to which the value written by software is ignored by hardware. Software may write any value to this field without affecting hardware behavior. Software reads of this field return the last value updated by hardware.</p> <p>If the Reset State of this field is “Undefined”, software reads of this field result in an UNPREDICTABLE value except after a hardware update done under the conditions specified in the description of the field.</p>
R0	<p>R0 = reserved, read as zero, ignore writes by software.</p> <p>Hardware ignores software writes to an R0 field. Neither the occurrence of such writes, nor the values written, affects hardware behavior.</p> <p>Hardware always returns 0 to software reads of R0 fields.</p> <p>The Reset State of an R0 field must always be 0.</p> <p>If software performs an mtc0 instruction which writes a non-zero value to an R0 field, the write to the R0 field will be ignored, but permitted writes to other fields in the register will not be affected.</p>	<p>Architectural Compatibility: R0 fields are reserved, and may be used for not-yet-defined purposes in future revisions of the architecture.</p> <p>When writing an R0 field, current software should only write either all 0s, or, preferably, write back the same value that was read from the field.</p> <p>Current software should not assume that the value read from R0 fields is zero, because this may not be true on future hardware.</p> <p>Future revisions of the architecture may redefine an R0 field, but must do so in such a way that software which is unaware of the new definition and either writes zeros or writes back the value it has read from the field will continue to work correctly.</p> <p>Writing back the same value that was read is guaranteed to have no unexpected effects on current or future hardware behavior. (Except for non-atomicity of such read-writes.)</p> <p>Writing zeros to an R0 field may not be preferred because in the future this may interfere with the operation of other software which has been updated for the new field definition.</p>

Table 1.2 Read/Write Register Field Notation (Continued)

Read/Write Notation	Hardware Interpretation	Software Interpretation
0	Release 6 Release 6 legacy “0” behaves like R0 - read as zero, nonzero writes ignored. Legacy “0” should not be defined for any new control register fields; R0 should be used instead.	
	HW returns 0 when read. HW ignores writes.	Only zero should be written, or, value read from register.
	pre-Release 6 pre-Release 6 legacy “0” - read as zero, nonzero writes UNDEFINED	
	A field which hardware does not update, and for which hardware can assume a zero value.	A field to which the value written by software must be zero. Software writes of non-zero values to this field may result in UNDEFINED behavior of the hardware. Software reads of this field return zero as long as all previous software writes are zero. If the Reset State of this field is “Undefined”, software must write this field with zero before it is guaranteed to read as zero.
R/W0	Like R/W, except that writes of non-zero to a R/W0 field are ignored. E.g. Status.NMI	
	Hardware may set or clear an R/W0 bit. Hardware ignores software writes of nonzero to an R/W0 field. Neither the occurrence of such writes, nor the values written, affects hardware behavior. Software writes of 0 to an R/W0 field may have an effect. Hardware may return 0 or nonzero to software reads of an R/W0 bit. If software performs an mtc0 instruction which writes a non-zero value to an R/W0 field, the write to the R/W0 field will be ignored, but permitted writes to other fields in the register will not be affected.	Software can only clear an R/W0 bit. Software writes 0 to an R/W0 field to clear the field. Software writes nonzero to an R/W0 bit in order to guarantee that the bit is not affected by the write.

1.5 For More Information

MIPS processor manuals and additional information about MIPS products can be found at <http://www.imgtec.com>.

Guide to the Instruction Set

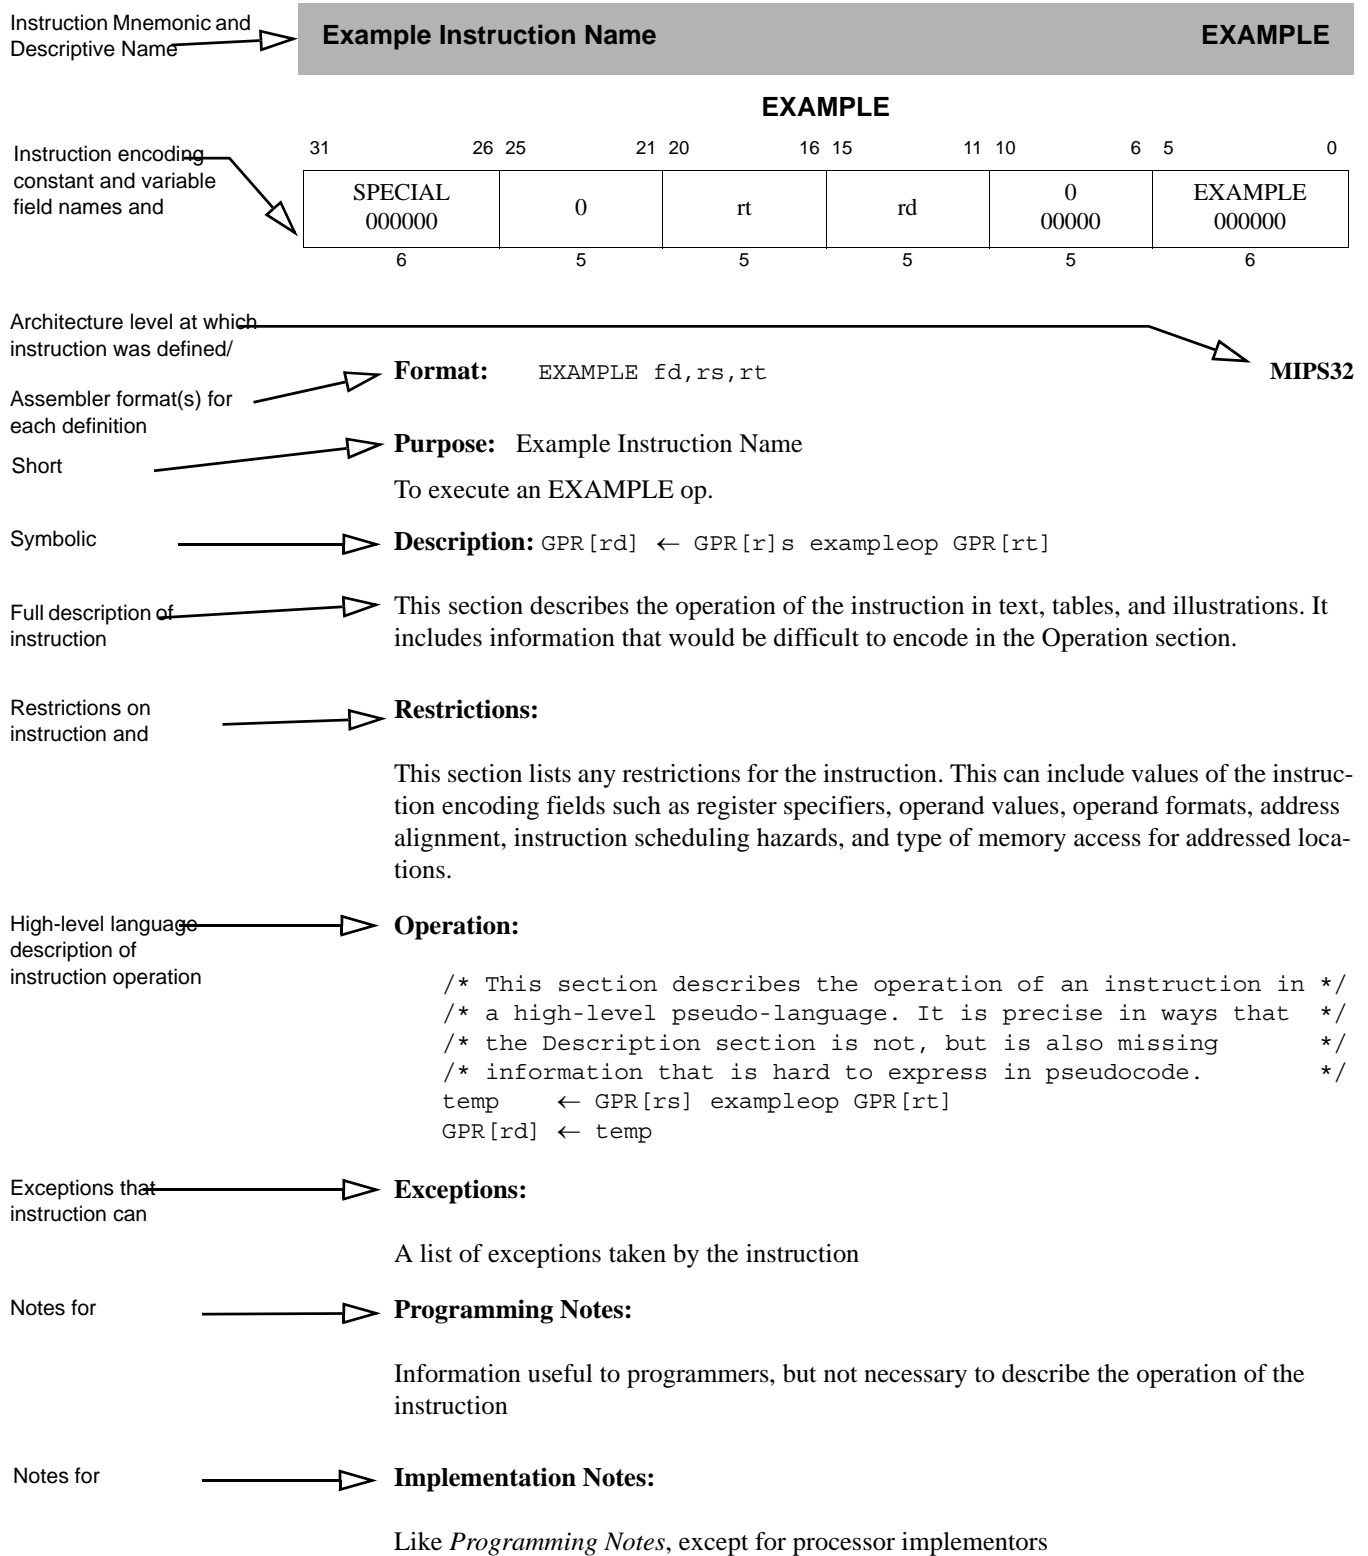

This chapter provides a detailed guide to understanding the instruction descriptions, which are listed in alphabetical order in the tables at the beginning of the next chapter.

2.1 Understanding the Instruction Fields

Figure 2.1 shows an example instruction. Following the figure are descriptions of the fields listed below:

- “Instruction Fields” on page 19
- “Instruction Descriptive Name and Mnemonic” on page 20
- “Format Field” on page 20
- “Purpose Field” on page 21
- “Description Field” on page 21
- “Restrictions Field” on page 21
- “Operation Field” on page 22
- “Exceptions Field” on page 23
- “Programming Notes and Implementation Notes Fields” on page 23

Figure 2.1 Example of Instruction Description

2.1.1 Instruction Fields

Fields encoding the instruction word are shown in register form at the top of the instruction description. The following rules are followed:

- The values of constant fields and the *opcode* names are listed in uppercase (SPECIAL and ADD in Figure 2.2). Constant values in a field are shown in binary below the symbolic or hexadecimal value.
- All variable fields are listed with the lowercase names used in the instruction description (*rs*, *rt*, and *rd* in Figure 2.2).
- Fields that contain zeros but are not named are unused fields that are required to be zero (bits 10:6 in Figure 2.2). If such fields are set to non-zero values, the operation of the processor is **UNPREDICTABLE**.

Figure 2.2 Example of Instruction Fields

2.1.2 Instruction Descriptive Name and Mnemonic

The instruction descriptive name and mnemonic are printed as page headings for each instruction, as shown in Figure 2.3.

Figure 2.3 Example of Instruction Descriptive Name and Mnemonic

2.1.3 Format Field

The assembler formats for the instruction and the architecture level at which the instruction was originally defined are given in the *Format* field. If the instruction definition was later extended, the architecture levels at which it was extended and the assembler formats for the extended definition are shown in their order of extension (for an example, see C.cond.fmt). The MIPS architecture levels are inclusive; higher architecture levels include all instructions in previous levels. Extensions to instructions are backwards compatible. The original assembler formats are valid for the extended architecture.

Figure 2.4 Example of Instruction Format

Format:	ADD fd,rs,rt	MIPS32
----------------	--------------	---------------

The assembler format is shown with literal parts of the assembler instruction printed in uppercase characters. The variable parts, the operands, are shown as the lowercase names of the appropriate fields.

The architectural level at which the instruction was first defined, for example “MIPS32” is shown at the right side of the page. Instructions introduced at different times by different ISA family members, are indicated by markings such as “MIPS64, MIPS32 Release 2”. Instructions removed by particular architecture release are indicated in the Availability section.

There can be more than one assembler format for each architecture level. Floating point operations on formatted data show an assembly format with the actual assembler mnemonic for each valid value of the *fmt* field. For example, the ADD.fmt instruction lists both ADD.S and ADD.D.

The assembler format lines sometimes include parenthetical comments to help explain variations in the formats (once again, see C.cond.fmt). These comments are not a part of the assembler format.

2.1.4 Purpose Field

The *Purpose* field gives a short description of the use of the instruction.

Figure 2.5 Example of Instruction Purpose

Purpose: Add Word

To add 32-bit integers. If an overflow occurs, then trap.

2.1.5 Description Field

If a one-line symbolic description of the instruction is feasible, it appears immediately to the right of the *Description* heading. The main purpose is to show how fields in the instruction are used in the arithmetic or logical operation.

Figure 2.6 Example of Instruction Description

Description: $\text{GPR}[rd] \leftarrow \text{GPR}[rs] + \text{GPR}[rt]$

The 32-bit word value in GPR *rt* is added to the 32-bit value in GPR *rs* to produce a 32-bit result.

- If the addition results in 32-bit 2's complement arithmetic overflow, the destination register is not modified and an Integer Overflow exception occurs.
- If the addition does not overflow, the 32-bit result is placed into GPR *rd*.

The body of the section is a description of the operation of the instruction in text, tables, and figures. This description complements the high-level language description in the *Operation* section.

This section uses acronyms for register descriptions. “GPR *rt*” is CPU general-purpose register specified by the instruction field *rt*. “FPR *fs*” is the floating point operand register specified by the instruction field *fs*. “CP1 register *fd*” is the coprocessor 1 general register specified by the instruction field *fd*. “FCSR” is the floating point *Control / Status* register.

2.1.6 Restrictions Field

The *Restrictions* field documents any possible restrictions that may affect the instruction. Most restrictions fall into one of the following six categories:

- Valid values for instruction fields (for example, see floating point ADD.fmt)
- ALIGNMENT requirements for memory addresses (for example, see LW)
- Valid values of operands (for example, see ALNV.PS)

- Valid operand formats (for example, see floating point ADD.fmt)
- Order of instructions necessary to guarantee correct execution. These ordering constraints avoid pipeline hazards for which some processors do not have hardware interlocks (for example, see MUL).
- Valid memory access types (for example, see LL/SC)

Figure 2.7 Example of Instruction Restrictions**Restrictions:**

None

2.1.7 Availability and Compatibility Fields

The *Availability* and *Compatibility* sections are not provided for all instructions. These sections list considerations relevant to whether and how an implementation may implement some instructions, when software may use such instructions, and how software can determine if an instruction or feature is present. Such considerations include:

- Some instructions are not present on all architecture releases. Sometimes the implementation is required to signal a Reserved Instruction exception, but sometimes executing such an instruction encoding is architecturally defined to give UNPREDICTABLE results.
- Some instructions are available for implementations of a particular architecture release, but may be provided only if an optional feature is implemented. Control register bits typically allow software to determine if the feature is present.
- Some instructions may not behave the same way on all implementations. Typically this involves behavior that was UNPREDICTABLE in some implementations, but which is made architectural and guaranteed consistent so that software can rely on it in subsequent architecture releases.
- Some instructions are prohibited for certain architecture releases and/or optional feature combinations.
- Some instructions may be removed for certain architecture releases. Implementations may then be required to signal a Reserved Instruction exception for the removed instruction encoding; but sometimes the instruction encoding is reused for other instructions.

All of these considerations may apply to the same instruction. If such considerations applicable to an instruction are simple, the architecture level in which an instruction was defined or redefined in the *Format* field, and/or the *Restrictions* section, may be sufficient; but if the set of such considerations applicable to an instruction is complicated, the *Availability* and *Compatibility* sections may be provided.

2.1.8 Operation Field

The *Operation* field describes the operation of the instruction as pseudocode in a high-level language notation resembling Pascal. This formal description complements the *Description* section; it is not complete in itself because many of the restrictions are either difficult to include in the pseudocode or are omitted for legibility.

Figure 2.8 Example of Instruction Operation**Operation:**

```

temp ← (GPR[rs]31 | GPR[rs]31..0) + (GPR[rt]31 | GPR[rt]31..0)
if temp32 ≠ temp31 then
    SignalException(IntegerOverflow)
else
    GPR[rd] ← temp
endif

```

See 2.2 “Operation Section Notation and Functions” on page 23 for more information on the formal notation used here.

2.1.9 Exceptions Field

The *Exceptions* field lists the exceptions that can be caused by *Operation* of the instruction. It omits exceptions that can be caused by the instruction fetch, for instance, TLB Refill, and also omits exceptions that can be caused by asynchronous external events such as an Interrupt. Although a Bus Error exception may be caused by the operation of a load or store instruction, this section does not list Bus Error for load and store instructions because the relationship between load and store instructions and external error indications, like Bus Error, are dependent upon the implementation.

Figure 2.9 Example of Instruction Exception**Exceptions:**

Integer Overflow

An instruction may cause implementation-dependent exceptions that are not present in the *Exceptions* section.

2.1.10 Programming Notes and Implementation Notes Fields

The *Notes* sections contain material that is useful for programmers and implementors, respectively, but that is not necessary to describe the instruction and does not belong in the description sections.

Figure 2.10 Example of Instruction Programming Notes**Programming Notes:**

ADDU performs the same arithmetic operation but does not trap on overflow.

2.2 Operation Section Notation and Functions

In an instruction description, the *Operation* section uses a high-level language notation to describe the operation performed by each instruction. Special symbols used in the pseudocode are described in the previous chapter. Specific pseudocode functions are described below.

This section presents information about the following topics:

- “Instruction Execution Ordering” on page 24

- “Pseudocode Functions” on page 24

2.2.1 Instruction Execution Ordering

Each of the high-level language statements in the *Operations* section are executed sequentially (except as constrained by conditional and loop constructs).

2.2.2 Pseudocode Functions

There are several functions used in the pseudocode descriptions. These are used either to make the pseudocode more readable, to abstract implementation-specific behavior, or both. These functions are defined in this section, and include the following:

- “Coprorocessor General Register Access Functions” on page 24
- “Memory Operation Functions” on page 26
- “Floating Point Functions” on page 29
- “Miscellaneous Functions” on page 33

2.2.2.1 Coprocessor General Register Access Functions

Defined coprocessors, except for CP0, have instructions to exchange words and doublewords between coprocessor general registers and the rest of the system. What a coprocessor does with a word or doubleword supplied to it and how a coprocessor supplies a word or doubleword is defined by the coprocessor itself. This behavior is abstracted into the functions described in this section.

2.2.2.1.1 COP_LW

The COP_LW function defines the action taken by coprocessor *z* when supplied with a word from memory during a load word operation. The action is coprocessor-specific. The typical action would be to store the contents of memword in coprocessor general register *rt*.

Figure 2.11 COP_LW Pseudocode Function

```
COP_LW (z, rt, memword)
  z: The coprocessor unit number
  rt: Coprocessor general register specifier
  memword: A 32-bit word value supplied to the coprocessor

  /* Coprocessor-dependent action */

endfunction COP_LW
```

2.2.2.1.2 COP_LD

The COP_LD function defines the action taken by coprocessor *z* when supplied with a doubleword from memory during a load doubleword operation. The action is coprocessor-specific. The typical action would be to store the contents of memdouble in coprocessor general register *rt*.

Figure 2.12 COP_LD Pseudocode Function

```
COP_LD (z, rt, memdouble)
```

```

z: The coprocessor unit number
rt: Coprocessor general register specifier
memdouble: 64-bit doubleword value supplied to the coprocessor.

/* Coprocessor-dependent action */

endfunction COP_LD

```

2.2.2.1.3 COP_SW

The COP_SW function defines the action taken by coprocessor *z* to supply a word of data during a store word operation. The action is coprocessor-specific. The typical action would be to supply the contents of the low-order word in coprocessor general register *rt*.

Figure 2.13 COP_SW Pseudocode Function

```

dataword ← COP_SW (z, rt)
z: The coprocessor unit number
rt: Coprocessor general register specifier
dataword: 32-bit word value

/* Coprocessor-dependent action */

endfunction COP_SW

```

2.2.2.1.4 COP_SD

The COP_SD function defines the action taken by coprocessor *z* to supply a doubleword of data during a store doubleword operation. The action is coprocessor-specific. The typical action would be to supply the contents of the low-order doubleword in coprocessor general register *rt*.

Figure 2.14 COP_SD Pseudocode Function

```

datadouble ← COP_SD (z, rt)
z: The coprocessor unit number
rt: Coprocessor general register specifier
datadouble: 64-bit doubleword value

/* Coprocessor-dependent action */

endfunction COP_SD

```

2.2.2.1.5 CoprocessorOperation

The CoprocessorOperation function performs the specified Coprocessor operation.

Figure 2.15 CoprocessorOperation Pseudocode Function

```

CoprocessorOperation (z, cop_fun)

/* z:          Coprocessor unit number */
/* cop_fun:    Coprocessor function from function field of instruction */

/* Transmit the cop_fun value to coprocessor z */

endfunction CoprocessorOperation

```

2.2.2.2 Memory Operation Functions

Regardless of byte ordering (big- or little-endian), the address of a halfword, word, or doubleword is the smallest byte address of the bytes that form the object. For big-endian ordering this is the most-significant byte; for a little-endian ordering this is the least-significant byte.

In the *Operation* pseudocode for load and store operations, the following functions summarize the handling of virtual addresses and the access of physical memory. The size of the data item to be loaded or stored is passed in the *AccessLength* field. The valid constant names and values are shown in Table 2.1. The bytes within the addressed unit of memory (word for 32-bit processors or doubleword for 64-bit processors) that are used can be determined directly from the *AccessLength* and the two or three low-order bits of the address.

2.2.2.2.1 Misaligned Support

MIPS processors originally required all memory accesses to be naturally aligned. MSA (the MIPS SIMD Architecture) supported misaligned memory accesses for its 128 bit packed SIMD vector loads and stores, from its introduction in MIPS Release 5. Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

The pseudocode function *MisalignedSupport* encapsulates the version number check to determine if misalignment is supported for an ordinary memory access.

Figure 2.16 MisalignedSupport Pseudocode Function

```
predicate ← MisalignedSupport ()
    return Config.AR ≥ 2 // Architecture Revision 2 corresponds to MIPS Release 6.
end function
```

See Appendix B, “Misaligned Memory Accesses” on page 511 for a more detailed discussion of misalignment, including pseudocode functions for the actual misaligned memory access.

2.2.2.2.2 AddressTranslation

The *AddressTranslation* function translates a virtual address to a physical address and its cacheability and coherency attribute, describing the mechanism used to resolve the memory reference.

Given the virtual address *vAddr*, and whether the reference is to Instructions or Data (*IorD*), find the corresponding physical address (*pAddr*) and the cacheability and coherency attribute (*CCA*) used to resolve the reference. If the virtual address is in one of the unmapped address spaces, the physical address and *CCA* are determined directly by the virtual address. If the virtual address is in one of the mapped address spaces then the TLB or fixed mapping MMU determines the physical address and access type; if the required translation is not present in the TLB or the desired access is not permitted, the function fails and an exception is taken.

Figure 2.17 AddressTranslation Pseudocode Function

```
(pAddr, CCA) ← AddressTranslation (vAddr, IorD, LorS)

/* pAddr: physical address */
/* CCA: Cacheability&Coherency Attribute, the method used to access caches */
/* and memory and resolve the reference */

/* vAddr: virtual address */
/* IorD: Indicates whether access is for INSTRUCTION or DATA */
/* LorS: Indicates whether access is for LOAD or STORE */
```

```

/* See the address translation description for the appropriate MMU */
/* type in Volume III of this book for the exact translation mechanism */

endfunction AddressTranslation

```

2.2.2.2.3 LoadMemory

The LoadMemory function loads a value from memory.

This action uses cache and main memory as specified in both the Cacheability and Coherency Attribute (*CCA*) and the access (*IorD*) to find the contents of *AccessLength* memory bytes, starting at physical location *pAddr*. The data is returned in a fixed-width naturally aligned memory element (*MemElem*). The low-order 2 (or 3) bits of the address and the *AccessLength* indicate which of the bytes within *MemElem* need to be passed to the processor. If the memory access type of the reference is *uncached*, only the referenced bytes are read from memory and marked as valid within the memory element. If the access type is *cached* but the data is not present in cache, an implementation-specific *size* and *alignment* block of memory is read and loaded into the cache to satisfy a load reference. At a minimum, this block is the entire memory element.

Figure 2.18 LoadMemory Pseudocode Function

```

MemElem ← LoadMemory (CCA, AccessLength, pAddr, vAddr, IorD)

/* MemElem: Data is returned in a fixed width with a natural alignment. The */
/*          width is the same size as the CPU general-purpose register, */
/*          32 or 64 bits, aligned on a 32- or 64-bit boundary, */
/*          respectively. */
/* CCA:      Cacheability&CoherencyAttribute=method used to access caches */
/*          and memory and resolve the reference */

/* AccessLength: Length, in bytes, of access */
/* pAddr:      physical address */
/* vAddr:      virtual address */
/* IorD:       Indicates whether access is for Instructions or Data */

endfunction LoadMemory

```

2.2.2.2.4 StoreMemory

The StoreMemory function stores a value to memory.

The specified data is stored into the physical location *pAddr* using the memory hierarchy (data caches and main memory) as specified by the Cacheability and Coherency Attribute (*CCA*). The *MemElem* contains the data for an aligned, fixed-width memory element (a word for 32-bit processors, a doubleword for 64-bit processors), though only the bytes that are actually stored to memory need be valid. The low-order two (or three) bits of *pAddr* and the *AccessLength* field indicate which of the bytes within the *MemElem* data should be stored; only these bytes in memory will actually be changed.

Figure 2.19 StoreMemory Pseudocode Function

```

StoreMemory (CCA, AccessLength, MemElem, pAddr, vAddr)

/* CCA:      Cacheability&Coherency Attribute, the method used to access */
/*          caches and memory and resolve the reference. */
/* AccessLength: Length, in bytes, of access */
/* MemElem:   Data in the width and alignment of a memory element. */

```

```

/*      The width is the same size as the CPU general */
/*      purpose register, either 4 or 8 bytes, */
/*      aligned on a 4- or 8-byte boundary. For a */
/*      partial-memory-element store, only the bytes that will be */
/*      stored must be valid. */
/* pAddr: physical address */
/* vAddr: virtual address */

endfunction StoreMemory

```

2.2.2.2.5 Prefetch

The Prefetch function prefetches data from memory.

Prefetch is an advisory instruction for which an implementation-specific action is taken. The action taken may increase performance but must not change the meaning of the program or alter architecturally visible state.

Figure 2.20 Prefetch Pseudocode Function

```

Prefetch (CCA, pAddr, vAddr, DATA, hint)

/* CCA:  Cacheability&Coherency Attribute, the method used to access */
/*      caches and memory and resolve the reference. */
/* pAddr: physical address */
/* vAddr: virtual address */
/* DATA: Indicates that access is for DATA */
/* hint:  hint that indicates the possible use of the data */

endfunction Prefetch

```

Table 2.1 lists the data access lengths and their labels for loads and stores.

Table 2.1 AccessLength Specifications for Loads/Stores

AccessLength Name	Value	Meaning
DOUBLEWORD	7	8 bytes (64 bits)
SEPTIBYTE	6	7 bytes (56 bits)
SEXTIBYTE	5	6 bytes (48 bits)
QUINTIBYTE	4	5 bytes (40 bits)
WORD	3	4 bytes (32 bits)
TRIPLEBYTE	2	3 bytes (24 bits)
HALFWORD	1	2 bytes (16 bits)
BYTE	0	1 byte (8 bits)

2.2.2.2.6 SyncOperation

The SyncOperation function orders loads and stores to synchronize shared memory.

This action makes the effects of the synchronizable loads and stores indicated by *stype* occur in the same order for all processors.

Figure 2.21 SyncOperation Pseudocode Function

```

SyncOperation(stype)

    /* stype: Type of load/store ordering to perform. */

    /* Perform implementation-dependent operation to complete the */
    /* required synchronization operation */

endfunction SyncOperation

```

2.2.2.3 Floating Point Functions

The pseudocode shown in below specifies how the unformatted contents loaded or moved to CP1 registers are interpreted to form a formatted value. If an FPR contains a value in some format, rather than unformatted contents from a load (uninterpreted), it is valid to interpret the value in that format (but not to interpret it in a different format).

2.2.2.3.1 ValueFPR

The ValueFPR function returns a formatted value from the floating point registers.

Figure 2.22 ValueFPR Pseudocode Function

```

value ← ValueFPR(fpr, fmt)

    /* value: The formatted value from the FPR */

    /* fpr:   The FPR number */
    /* fmt:   The format of the data, one of: */
    /*        S, D, W, L, PS, */
    /*        OB, QH, */
    /*        UNINTERPRETED_WORD, */
    /*        UNINTERPRETED_DOUBLEWORD */
    /* The UNINTERPRETED values are used to indicate that the datatype */
    /* is not known as, for example, in SWC1 and SDC1 */

    case fmt of
        S, W, UNINTERPRETED_WORD:
            valueFPR ← FPR[fpr]

        D, UNINTERPRETED_DOUBLEWORD:
            if (FP32RegistersMode = 0)
                if (fpr0 ≠ 0) then
                    valueFPR ← UNPREDICTABLE
                else
                    valueFPR ← FPR[fpr+1]31..0 || FPR[fpr]31..0
                endif
            else
                valueFPR ← FPR[fpr]
            endif

        L, PS:
            if (FP32RegistersMode = 0) then
                valueFPR ← UNPREDICTABLE
            else
                valueFPR ← FPR[fpr]
            endif
    endcase

```

```

    DEFAULT:
        valueFPR ← UNPREDICTABLE

    endcase
endfunction ValueFPR

```

The pseudocode shown below specifies the way a binary encoding representing a formatted value is stored into CP1 registers by a computational or move operation. This binary representation is visible to store or move-from instructions. Once an FPR receives a value from the StoreFPR(), it is not valid to interpret the value with ValueFPR() in a different format.

2.2.2.3.2 StoreFPR

Figure 2.23 StoreFPR Pseudocode Function

```

StoreFPR (fpr, fmt, value)

/* fpr:   The FPR number */
/* fmt:   The format of the data, one of: */
/*        S, D, W, L, PS, */
/*        OB, QH, */
/*        UNINTERPRETED_WORD, */
/*        UNINTERPRETED_DOUBLEWORD */
/* value: The formatted value to be stored into the FPR */

/* The UNINTERPRETED values are used to indicate that the datatype */
/* is not known as, for example, in LWC1 and LDC1 */

case fmt of
    S, W, UNINTERPRETED_WORD:
        FPR[fpr] ← value

    D, UNINTERPRETED_DOUBLEWORD:
        if (FP32RegistersMode = 0)
            if (fpr0 ≠ 0) then
                UNPREDICTABLE
            else
                FPR[fpr]   ← UNPREDICTABLE32 || value31..0
                FPR[fpr+1] ← UNPREDICTABLE32 || value63..32
            endif
        else
            FPR[fpr] ← value
        endif

    L, PS:
        if (FP32RegistersMode = 0) then
            UNPREDICTABLE
        else
            FPR[fpr] ← value
        endif

endcase

endfunction StoreFPR

```

2.2.2.3.3 CheckFPException

The pseudocode shown below checks for an enabled floating point exception and conditionally signals the exception.

Figure 2.24 CheckFPException Pseudocode Function

```

CheckFPException()

/* A floating point exception is signaled if the E bit of the Cause field is a 1 */
/* (Unimplemented Operations have no enable) or if any bit in the Cause field */
/* and the corresponding bit in the Enable field are both 1 */

    if ( (FCSR17 = 1) or
          ((FCSR16..12 and FCSR11..7) ≠ 0)) ) then
        SignalException(FloatingPointException)
    endif

endfunction CheckFPException

```

2.2.2.3.4 FPConditionCode

The FPConditionCode function returns the value of a specific floating point condition code.

Figure 2.25 FPConditionCode Pseudocode Function

```

tf ← FPConditionCode(cc)

/* tf: The value of the specified condition code */

/* cc: The Condition code number in the range 0..7 */

if cc = 0 then
    FPConditionCode ← FCSR23
else
    FPConditionCode ← FCSR24+cc
endif

endfunction FPConditionCode

```

2.2.2.3.5 SetFPConditionCode

The SetFPConditionCode function writes a new value to a specific floating point condition code.

Figure 2.26 SetFPConditionCode Pseudocode Function

```

SetFPConditionCode(cc, tf)
    if cc = 0 then
        FCSR ← FCSR31..24 || tf || FCSR22..0
    else
        FCSR ← FCSR31..25+cc || tf || FCSR23+cc..0
    endif

endfunction SetFPConditionCode

```

2.2.2.4 Pseudocode Functions Related to Sign and Zero Extension

2.2.2.4.1 Sign extension and zero extension in pseudocode

Much pseudocode uses a generic function `sign_extend` without specifying from what bit position the extension is done, when the intention is obvious. E.g. `sign_extend(immediate16)` or `sign_extend(dispatch9)`.

However, sometimes it is necessary to specify the bit position. For example, `sign_extend(temp31..0)` or the more complicated `(offset15)GPRLEN-(16+2) || offset || 02`.

The explicit notation `sign_extend.nbits(val)` or `sign_extend(val, nbits)` is suggested as a simplification. They say to sign extend as if an `nbits`-sized signed integer. The width to be sign extended to is usually apparent by context, and is usually `GPRLEN`, 32 or 64 bits. The previous examples then become.

```
sign_extend(temp31..0)
= sign_extend.32(temp)
```

and

```
(offset15)GPRLEN-(16+2) || offset || 02
= sign_extend.16(offset) << 2
```

Note that `sign_extend.N(value)` extends from bit position `N-1`, if the bits are numbered `0..N-1` as is typical.

The explicit notations `sign_extend.nbits(val)` or `sign_extend(val, nbits)` is used as a simplification. These notations say to sign extend as if an `nbits`-sized signed integer. The width to be sign extended to is usually apparent by context, and is usually `GPRLEN`, 32 or 64 bits.

Figure 2.27 sign_extend Pseudocode Functions

```
sign_extend.nbits(val) = sign_extend(val, nbits) /* syntactic equivalents */

function sign_extend(val, nbits)
  return (valnbits-1)GPRLEN-nbits || valnbits-1..0
end function
```

The earlier examples can be expressed as

```
(offset15)GPRLEN-(16+2) || offset || 02
= sign_extend.16(offset) << 2
```

and

```
sign_extend(temp31..0)
= sign_extend.32(temp)
```

Similarly for `zero_extension`, although zero extension is less common than sign extension in the MIPS ISA.

Floating point may use notations such as `zero_extend.fmt` corresponding to the format of the FPU instruction. E.g. `zero_extend.S` and `zero_extend.D` are equivalent to `zero_extend.32` and `zero_extend.64`.

Existing pseudocode may use any of these, or other, notations. TBD: rewrite pseudocode.

2.2.2.4.2 memory_address

The pseudocode function `memory_address` performs mode-dependent address space wrapping for compatibility between MIPS32 and MIPS64. It is applied to all memory references. It may be specified explicitly in some places, particularly for new memory reference instructions, but it is also declared to apply implicitly to all memory refer-

ences as defined below. In addition, certain instructions that are used to calculate effective memory addresses but which are not themselves memory accesses specify `memory_address` explicitly in their pseudocode.

Figure 2.28 `memory_address` Pseudocode Function

```
function memory_address(ea)
    return ea
end function
```

On a 32-bit CPU, `memory_address` returns its 32-bit effective address argument unaffected.

In addition to the use of `memory_address` for all memory references (including load and store instructions, LL/SC), Release 6 extends this behavior to control transfers (branch and call instructions), and to the PC-relative address calculation instructions (ADDIUPC, AUIPC, ALUIPC). In newer instructions the function is explicit in the pseudocode.

Implicit address space wrapping for all instruction fetches is described by the following pseudocode fragment which should be considered part of instruction fetch:

Figure 2.29 Instruction Fetch Implicit `memory_address` Wrapping

```
PC ← memory_address( PC )
( instruction_data, length ) ← instruction_fetch( PC )
/* decode and execute instruction */
```

Implicit address space wrapping for all data memory accesses is described by the following pseudocode, which is inserted at the top of the `AddressTranslation` pseudocode function:

Figure 2.30 `AddressTranslation` implicit `memory_address` Wrapping

```
(pAddr, CCA) ← AddressTranslation (vAddr, IorD, LorS)
vAddr ← memory_address(vAddr)
```

In addition to its use in instruction pseudocode,

2.2.2.5 Miscellaneous Functions

This section lists miscellaneous functions not covered in previous sections.

2.2.2.5.1 `SignalException`

The `SignalException` function signals an exception condition.

This action results in an exception that aborts the instruction. The instruction operation pseudocode never sees a return from this function call.

Figure 2.31 `SignalException` Pseudocode Function

```
SignalException(Exception, argument)

/* Exception:    The exception condition that exists. */
/* argument:     A exception-dependent argument, if any */

endfunction SignalException
```

2.2.2.5.2 SignalDebugBreakpointException

The SignalDebugBreakpointException function signals a condition that causes entry into Debug Mode from non-Debug Mode.

This action results in an exception that aborts the instruction. The instruction operation pseudocode never sees a return from this function call.

Figure 2.32 SignalDebugBreakpointException Pseudocode Function

```
SignalDebugBreakpointException()

endfunction SignalDebugBreakpointException
```

2.2.2.5.3 SignalDebugModeBreakpointException

The SignalDebugModeBreakpointException function signals a condition that causes entry into Debug Mode from Debug Mode (i.e., an exception generated while already running in Debug Mode).

This action results in an exception that aborts the instruction. The instruction operation pseudocode never sees a return from this function call.

Figure 2.33 SignalDebugModeBreakpointException Pseudocode Function

```
SignalDebugModeBreakpointException()

endfunction SignalDebugModeBreakpointException
```

2.2.2.5.4 NullifyCurrentInstruction

The NullifyCurrentInstruction function nullifies the current instruction.

The instruction is aborted, inhibiting not only the functional effect of the instruction, but also inhibiting all exceptions detected during fetch, decode, or execution of the instruction in question. For branch-likely instructions, nullification kills the instruction in the delay slot of the branch likely instruction.

Figure 2.34 NullifyCurrentInstruction PseudoCode Function

```
NullifyCurrentInstruction()

endfunction NullifyCurrentInstruction
```

2.2.2.5.5 JumpDelaySlot

The JumpDelaySlot function is used in the pseudocode for the PC-relative instructions in the MIPS16e ASE. The function returns TRUE if the instruction at *vAddr* is executed in a jump delay slot. A jump delay slot always immediately follows a JR, JAL, JALR, or JALX instruction.

Figure 2.35 JumpDelaySlot Pseudocode Function

```
JumpDelaySlot(vAddr)

/* vAddr:Virtual address */

endfunction JumpDelaySlot
```

2.2.2.5.6 PolyMult

The PolyMult function multiplies two binary polynomial coefficients.

Figure 2.36 PolyMult Pseudocode Function

```
PolyMult(x, y)
    temp ← 0
    for i in 0 .. 31
        if xi = 1 then
            temp ← temp xor (Y(31-i)..0 || 0i)
        endif
    endfor

    PolyMult ← temp

endfunction PolyMult
```

2.3 Op and Function Subfield Notation

In some instructions, the instruction subfields *op* and *function* can have constant 5- or 6-bit values. When reference is made to these instructions, uppercase mnemonics are used. For instance, in the floating point ADD instruction, *op*=COP1 and *function*=ADD. In other cases, a single field has both fixed and variable subfields, so the name contains both upper- and lowercase characters.

2.4 FPU Instructions

In the detailed description of each FPU instruction, all variable subfields in an instruction format (such as *fs*, *ft*, *immediate*, and so on) are shown in lowercase. The instruction name (such as ADD, SUB, and so on) is shown in uppercase.

For the sake of clarity, an alias is sometimes used for a variable subfield in the formats of specific instructions. For example, *rs=base* in the format for load and store instructions. Such an alias is always lowercase since it refers to a variable subfield.

Bit encodings for mnemonics are given in Volume I, in the chapters describing the CPU, FPU, MDMX, and MIPS16e instructions.

See “Op and Function Subfield Notation” on page 35 for a description of the *op* and *function* subfields.

The MIPS32® Instruction Set

3.1 Compliance and Subsetting

To be compliant with the MIPS32 Architecture, designs must implement a set of required features, as described in this document set. To allow implementation flexibility, the MIPS32 Architecture provides subsetting rules. An implementation that follows these rules is compliant with the MIPS32 Architecture as long as it adheres strictly to the rules, and fully implements the remaining instructions. Supersetting of the MIPS32 Architecture is only allowed by adding functions to the *SPECIAL2*, *COP2*, or both major opcodes, by adding control for co-processors via the *COP2*, *LWC2*, *SWC2*, *LDC2*, and/or *SDC2*, or via the addition of approved Application Specific Extensions.

Release 6 removes all instructions under the *SPECIAL2* major opcode, either by removing them or moving them to the *COP2* major opcode. All coprocessor 2 support instructions (for example, *LWC2*) have been moved to the *COP2* major opcode. Supersetting of the Release 6 architecture is only allowed in the *COP2* major opcode, or via the addition of approved Application Specific Extensions. *SPECIAL2* is reserved for MIPS.

Note: The use of *COP3* as a customizable coprocessor has been removed in the Release 2 of the MIPS32 architecture. The *COP3* is reserved for the future extension of the architecture. Implementations using Release1 of the MIPS32 architecture are strongly discouraged from using the *COP3* opcode for a user-available coprocessor as doing so will limit the potential for an upgrade path to a 64-bit floating point unit.

The instruction set subsetting rules are described in the subsections below, and also the following rule:

- **Co-dependence of Architecture Features:** MIPSr5™ (also called Release 5) and subsequent releases (such as Release 6) include a number of features. Some are optional; some are required. Features provided by a release, such as MIPSr5 or later, whether optional or required, must be consistent. If any feature that is introduced by a particular release is implemented (such as a feature described as part of Release 5 and not any earlier release) then all other features must be implemented in a manner consistent with that release. For example: the VZ and MSA features are introduced by Release 5 but are optional. The FR=1 64-bit FPU register model was optional when introduced earlier, but is now required by Release 5 if any FPU is implemented. If any or all of VZ or MSA are implemented, then Release 5 is implied, and then if an FPU is implemented, it must implement the FR=1 64-bit FPU register model.

3.1.1 Subsetting of Non-Privileged Architecture

- All non-privileged (do not need access to Coprocessor 0) CPU (non-FPU) instructions must be implemented — no subsetting of these are allowed — per the MIPS Instruction Set Architecture release supported.
- If any instruction is subsetting out based on the rules below, an attempt to execute that instruction must cause the appropriate exception (typically Reserved Instruction or Coprocessor Unusable).
- The FPU and related support instructions, such as CPU conditional branches on FPU conditions (pre-Release 6 BC1T/BC1F, Release 6 BC1NEQZ) and CPU conditional moves on FPU conditions (pre-Release 6 MOVT/ MOVF), may be omitted. Software may determine if an FPU is implemented by checking the state of the FP bit in the *Config1* CP0 register. Software may determine which FPU data types are implemented by checking the

appropriate bits in the *FIR* CP1 register. The following allowable FPU subsets are compliant with the MIPS32 architecture:

- No FPU

Config1.FP=0

- FPU with S, and W formats and all supporting instructions.

This 32-bit subset is permitted by Release 6, but prohibited by pre-Release 6 releases.

Config1.FP=1, *Status*.FR=0, *FIR*.S=*FIR*.L=1, *FIR*.D=*FIR*.L=*FIR*.PS=0.

- FPU with S, D, W, and L formats and all supporting instructions

Config1.FP=1, *Status*.FR=(see below), *FIR*.S=*FIR*.L=*FIR*.D=*FIR*.L=1, *FIR*.PS=0.

pre-MIPSR5 permits this 64-bit configuration, and allows both FPU register modes. *Status*.FR=0 support is required but *Status*.FR=1 support is optional.

MIPSR5 permits this 64-bit configuration, and requires both FPU register modes, i.e. both *Status*.FR=0 and *Status*.FR=1 support are required.

Release 6 permits this 64-bit configuration, but requires *Status*.FR=1 and *FIR*.F64=1. Release 6 prohibits *Status*.FR=0 if *FIR*.D=1 or *FIR*.L=1.

- FPU with S, D, PS, W, and L formats and all supporting instructions

Config1.FP=1, *Status*.FR=0/1, *FIR*.S=*FIR*.L=*FIR*.D=*FIR*.L=*FIR*.PS=1.

Release 6 prohibits this mode, and any mode with *FIR*.PS=1 paired single support.

- In Release 5 of the Architecture, if floating point is implemented then FR=1 is required. I.e. the 64-bit FPU, with the FR=1 64-bit FPU register model, is required. The FR=0 32-bit FPU register model continues to be required.

- Coprocessor 2 is optional and may be omitted. Software may determine if Coprocessor 2 is implemented by checking the state of the C2 bit in the *Config1* CP0 register. If Coprocessor 2 is implemented, the Coprocessor 2 interface instructions (BC2, CFC2, COP2, CTC2, LDC2, LWC2, MFC2, MTC2, SDC2, and SWC2) may be omitted on an instruction-by-instruction basis.
- The caches are optional. The *Config1*_{DL} and *Config1*_{IL} fields denote whether the first level caches are present or not.
- Instruction, CP0 Register, and CP1 Control Register fields that are marked “Reserved” or shown as “0” in the description of that field are reserved for future use by the architecture and are not available to implementations. Implementations may only use those fields that are explicitly reserved for implementation dependent use.
- Supported Modules/ASEs are optional and may be subsetting out. In most cases, software may determine if a supported Module/ASE is implemented by checking the appropriate bit in the *Config1* or *Config3* or *Config4* CP0 register. If they are implemented, they must implement the entire ISA applicable to the component, or implement subsets that are approved by the Module/ASE specifications.

- EJTAG is optional and may be subsetted out. If it is implemented, it must implement only those subsets that are approved by the EJTAG specification. If EJTAG is not implemented, the EJTAG instructions (SDBBP and DERET) can be subsetted out.
- In MIPSr3 (also called Release 3), there are two architecture branches (MIPS32/64 and microMIPS32/64). A single device is allowed to implement both architecture branches. The Privileged Resource Architecture (COP0) registers do not mode-switch in width (32-bit vs. 64-bit). For this reason, if a device implements both architecture branches, the address/data widths must be consistent. If a device implements MIPS64 and also implements microMIPS, it must implement microMIPS64 not just microMIPS32. Similarly, If a device implements microMIPS64 and also implements MIPS32/64, it must implement MIPS64 not just MIPS32.
- The JALX instruction is required if and only if ISA mode-switching is possible. If both of the architecture branches are implemented (MIPS32/64 and microMIPS32/64) or if MIPS16e is implemented then the JALX instructions are required. If only one branch of the architecture family and MIPS16e is not implemented then the JALX instruction is not implemented.

3.2 Alphabetical List of Instructions

The following pages present detailed descriptions of instructions, arranged alphabetical order of opcode mnemonic (except where several similar instructions are described together.)

Format: ABS.fmt
 ABS.S fd, fs
 ABS.D fd, fs
 ABS.PS fd, fs

MIPS32
MIPS32
MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Absolute Value

Description: $FPR[fd] \leftarrow abs(FPR[fs])$

The absolute value of the value in FPR *fs* is placed in FPR *fd*. The operand and result are values in format *fmt*. ABS.PS takes the absolute value of the two values in FPR *fs* independently, and ORs together any generated exceptions.

The *Cause* bits are ORed into the *Flag* bits if no exception is taken.

If $FIR_{Has2008}=0$ or $FCSR_{ABS2008}=0$ then this operation is arithmetic. For this case, any NaN operand signals invalid operation.

If $FCSR_{ABS2008}=1$ then this operation is non-arithmetic. For this case, both regular floating point numbers and NaN values are treated alike, only the sign bit is affected by this instruction. No IEEE exception can be generated for this case.

Restrictions:

The fields *fs* and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of ABS.PS is **UNPREDICTABLE** if the processor is executing in the $FR=0$ 32-bit FPU register model. ABS.PS is predictable if executing on a 64-bit FPU in the $FR=1$ mode, but not with $FR=0$, and not on a 32-bit FPU.

Availability and Compatibility:

The ABS.PS instruction has been removed in Release 6.

Operation:

```
StoreFPR(fd, fmt, AbsoluteValue(ValueFPR(fs, fmt)))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation, Invalid Operation

Format: ADD *rd*, *rs*, *rt*

MIPS32

Purpose: Add Word

To add 32-bit integers. If an overflow occurs, then trap.

Description: $GPR[rd] \leftarrow GPR[rs] + GPR[rt]$

The 32-bit word value in GPR *rt* is added to the 32-bit value in GPR *rs* to produce a 32-bit result.

- If the addition results in 32-bit 2's complement arithmetic overflow, the destination register is not modified and an Integer Overflow exception occurs.
- If the addition does not overflow, the 32-bit result is placed into GPR *rd*.

Restrictions:

None

Operation:

```
temp ← (GPR[rs]31 | GPR[rs]31..0) + (GPR[rt]31 | GPR[rt]31..0)
if temp32 ≠ temp31 then
    SignalException(IntegerOverflow)
else
    GPR[rd] ← temp
endif
```

Exceptions:

Integer Overflow

Programming Notes:

ADDU performs the same arithmetic operation but does not trap on overflow.

Format: ADD.fmt
 ADD.S fd, fs, ft
 ADD.D fd, fs, ft
 ADD.PS fd, fs, ft

MIPS32
MIPS32
MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Add

To add floating point values.

Description: $FPR[fd] \leftarrow FPR[fs] + FPR[ft]$

The value in FPR *ft* is added to the value in FPR *fs*. The result is calculated to infinite precision, rounded by using to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operands and result are values in format *fmt*.

ADD.PS adds the upper and lower halves of FPR *fs* and FPR *ft* independently, and ORs together any generated exceptions.

The *Cause* bits are ORed into the *Flag* bits if no exception is taken.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*. If the fields are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of ADD.PS is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. ADD.PS is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

The ADD.PS instruction has been removed in Release 6.

Operation:

StoreFPR (fd, fmt, ValueFPR(fs, fmt) +_{fmt} ValueFPR(ft, fmt))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation, Invalid Operation, Inexact, Overflow, Underflow

Format: ADDI *rt*, *rs*, *immediate*

MIPS32, removed in Release 6

Purpose: Add Immediate Word

To add a constant to a 32-bit integer. If overflow occurs, then trap.

Description: $GPR[rt] \leftarrow GPR[rs] + \text{immediate}$

The 16-bit signed *immediate* is added to the 32-bit value in GPR *rs* to produce a 32-bit result.

- If the addition results in 32-bit 2's complement arithmetic overflow, the destination register is not modified and an Integer Overflow exception occurs.
- If the addition does not overflow, the 32-bit result is placed into GPR *rt*.

Restrictions:

Availability and Compatibility:

This instruction has been removed in Release 6. The encoding has been reused for other instructions introduced by Release 6.

Operation:

```
temp ← (GPR[rs]31 || GPR[rs]31..0) + sign_extend(immediate)
if temp32 ≠ temp31 then
    SignalException(IntegerOverflow)
else
    GPR[rt] ← temp
endif
```

Exceptions:

Integer Overflow

Programming Notes:

ADDIU performs the same arithmetic operation but does not trap on overflow.

31	26	25	21	20	16	15	0
ADDIU 001001		rs		rt		immediate	
6		5		5		16	

Format: ADDIU *rt*, *rs*, *immediate*

MIPS32

Purpose: Add Immediate Unsigned Word

To add a constant to a 32-bit integer.

Description: $\text{GPR}[\text{rt}] \leftarrow \text{GPR}[\text{rs}] + \text{immediate}$

The 16-bit signed *immediate* is added to the 32-bit value in GPR *rs* and the 32-bit arithmetic result is placed into GPR *rt*.

No Integer Overflow exception occurs under any circumstances.

Restrictions:

None

Operation:

```
temp ← GPR[rs] + sign_extend(immediate)
GPR[rt] ← temp
```

Exceptions:

None

Programming Notes:

The term “unsigned” in the instruction name is a misnomer; this operation is 32-bit modulo arithmetic that does not trap on overflow. This instruction is appropriate for unsigned arithmetic, such as address arithmetic, or integer arithmetic environments that ignore overflow, such as C language arithmetic.

Format: ADDIUPC rs,immediate

MIPS32 Release 6

Purpose: Add Immediate to PC (unsigned - non-trapping)¹

Description: $GPR[rs] \leftarrow (PC + \text{sign_extend}(\text{immediate} \ll 2))$

This instruction performs a PC-relative address calculation. The 19-bit immediate is shifted left by 2 bits, sign-extended, and added to the address of the ADDIUPC instruction. The result is placed in GPR *rs*.

Restrictions:

None

Availability and Compatibility:

This instruction is introduced by and required as of Release 6.

Operation:

$GPR[rd] \leftarrow (PC + \text{sign_extend}(\text{immediate} \ll 2))$

Exceptions:

None

-
1. The term “unsigned” in this instruction mnemonic is a misnomer. “Unsigned:” here means “non-trapping”. It does not trap on a signed 32-bit overflow, the way pre-Release 6 ADD and ADDI do. ADDIUPC corresponds to unsigned ADDIU or ADDU, which do not trap on overflow, rather than ADDI, which traps on overflow.

Format: ADDU rd, rs, rt

MIPS32

Purpose: Add Unsigned Word

To add 32-bit integers.

Description: $GPR[rd] \leftarrow GPR[rs] + GPR[rt]$

The 32-bit word value in GPR *rt* is added to the 32-bit value in GPR *rs* and the 32-bit arithmetic result is placed into GPR *rd*.

No Integer Overflow exception occurs under any circumstances.

Restrictions:

None

Operation:

```
temp ← GPR[rs] + GPR[rt]
GPR[rd] ← temp
```

Exceptions:

None

Programming Notes:

The term “unsigned” in the instruction name is a misnomer; this operation is 32-bit modulo arithmetic that does not trap on overflow. This instruction is appropriate for unsigned arithmetic, such as address arithmetic, or integer arithmetic environments that ignore overflow, such as C language arithmetic.

31	26	25	21	20	16	15	11	10	8	7	6	5	0
SPECIAL3 011111	rs	rt	rd	ALIGN 010	bp	BSHFL 100000							
6	5	5	5	3	2	6							

Format: ALIGN
ALIGN rd,rs,rt,bp

MIPS32 Release 6

Purpose: Concatenate two GPRs, and extract a contiguous subset at a byte position

Description: $\text{GPR}[\text{rd}] \leftarrow (\text{GPR}[\text{rt}] \ll (8 * \text{bp})) \text{ or } (\text{GPR}[\text{rs}] \gg (\text{GPRLEN} - 8 * \text{bp}))$

The input registers GPR *rt* and GPR *rs* are concatenated, and a register width contiguous subset is extracted, which is specified by the byte pointer *bp*.

The ALIGN instruction operates on 32-bit words, and has a 2-bit byte position field *bp*.

- The 32-bit word in GPR *rt* is left shifted as a 32-bit value by *bp* byte positions. The 32-bit word in register *rs* is right shifted as a 32-bit value by $(4 - \text{bp})$ byte positions. These shifts are logical shifts, zero-filling. The shifted values are then *or*-ed together to create a 32-bit result that written to destination GPR *rd*.

Restrictions:

Executing ALIGN with shift count *bp*=0 acts like a register to register move operation, is redundant with other such, and is therefore discouraged. Software should not generate ALIGN with shift count *bp*=0.

Availability and Compatibility:

The ALIGN instruction is introduced by and required as of Release 6.

Programming Notes:

Release 6 ALIGN instruction corresponds to the pre-Release 6 DSP Module BALIGN instruction, except that BALIGN with shift counts of 0 and 2 are specified as being UNPREDICTABLE, whereas ALIGN defines all *bp* values, discouraging only *bp*=0.

Graphically,

Figure 3.1 ALIGN operation (32-bit)

Operation:

```
tmp_rt_hi ← unsigned_word(GPR[rt]) << (8 * bp)
tmp_rs_lo ← unsigned_word(GPR[rs]) >> (8 * (4 - bp))
tmp ← tmp_rt_hi or tmp_rs_lo
```

ALIGN**Concatenate two GPRs, and extract a contiguous subset at a byte position**

```
GPR[rd] ← tmp  
/* end of instruction */
```

Exceptions:

None

Format: ALNV.PS *fd, fs, ft, rs*

MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Align Variable

To align a misaligned pair of paired single values.

Description: $FPR[fd] \leftarrow \text{ByteAlign}(GPR[rs]_{2..0}, FPR[fs], FPR[ft])$

FPR *fs* is concatenated with FPR *ft* and this value is funnel-shifted by GPR *rs*_{2..0} bytes, and written into FPR *fd*. If GPR *rs*_{2..0} is 0, FPR *fd* receives FPR *fs*. If GPR *rs*_{2..0} is 4, the operation depends on the current endianness.

Figure 3-1 illustrates the following example: for a big-endian operation and a byte alignment of 4, the upper half of FPR *fd* receives the lower half of the paired single value in *fs*, and the lower half of FPR *fd* receives the upper half of the paired single value in FPR *ft*.

Figure 3.2 Example of an ALNV.PS Operation

The move is non arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *PS*. If the fields are not valid, the result is **UNPREDICTABLE**.

If GPR *rs*_{1..0} are non-zero, the results are **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. The instruction is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```
if GPR[rs]2..0 = 0 then
    StoreFPR(fd, PS, ValueFPR(fs, PS))
```

```

else if GPR[rs]2..0 ≠ 4 then
    UNPREDICTABLE
else if BigEndianCPU then
    StoreFPR(fd, PS, ValueFPR(fs, PS)31..0 || ValueFPR(ft,PS)63..32)
else
    StoreFPR(fd, PS, ValueFPR(ft, PS)31..0 || ValueFPR(fs,PS)63..32)
endif

```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Programming Notes:

ALNV.PS is designed to be used with LUXC1 to load 8 bytes of data from any 4-byte boundary. For example:

```

/* Copy T2 bytes (a multiple of 16) of data T0 to T1, T0 unaligned, T1 aligned.
   Reads one dw beyond the end of T0. */
LUXC1    F0, 0(T0) /* set up by reading 1st src dw */
LI       T3, 0     /* index into src and dst arrays */
ADDIU    T4, T0, 8 /* base for odd dw loads */
ADDIU    T5, T1, -8/* base for odd dw stores */
LOOP:
LUXC1    F1, T3(T4)
ALNV.PS  F2, F0, F1, T0/* switch F0, F1 for little-endian */
SDC1     F2, T3(T1)
ADDIU    T3, T3, 16
LUXC1    F0, T3(T0)
ALNV.PS  F2, F1, F0, T0/* switch F1, F0 for little-endian */
BNE      T3, T2, LOOP
SDC1     F2, T3(T5)
DONE:

```

ALNV.PS is also useful with SUXC1 to store paired-single results in a vector loop to a possibly misaligned address:

```

/* T1[i] = T0[i] + F8, T0 aligned, T1 unaligned. */
   CVT.PS.S F8, F8, F8/* make addend paired-single */

/* Loop header computes 1st pair into F0, stores high half if T1 */
/* misaligned */

LOOP:
LDC1     F2, T3(T4)/* get T0[i+2]/T0[i+3] */
ADD.PS   F1, F2, F8/* compute T1[i+2]/T1[i+3] */
ALNV.PS  F3, F0, F1, T1/* align to dst memory */
SUXC1    F3, T3(T1)/* store to T1[i+0]/T1[i+1] */
ADDIU    T3, 16     /* i = i + 4 */
LDC1     F2, T3(T0)/* get T0[i+0]/T0[i+1] */
ADD.PS   F0, F2, F8/* compute T1[i+0]/T1[i+1] */
ALNV.PS  F3, F1, F0, T1/* align to dst memory */
BNE      T3, T2, LOOP
SUXC1    F3, T3(T5)/* store to T1[i+2]/T1[i+3] */

/* Loop trailer stores all or half of F0, depending on T1 alignment */

```

Format: ALUIPC *rs*,immediate

MIPS32 Release 6

Purpose: Aligned Add Upper Immediate to PC

Description: $\sim 0x0FFFF \& (PC + (immediate \ll 16))$

This instruction performs a PC-relative address calculation. The 16-bit immediate is shifted left by 16 bits, sign-extended, and added to the address of the ALUIPC instruction. The low 16 bits of the result are cleared, that is the result is aligned on a 64K boundary. The result is placed in GPR *rs*.

Restrictions:

None

Availability and Compatibility:

This instruction is introduced by and required as of Release 6.

Operation:

$GPR[rs] \leftarrow \sim 0x0FFFF \& (PC + sign_extend(immediate \ll 16))$

Exceptions:

None

Format: AND rd, rs, rt

MIPS32

Purpose: And

To do a bitwise logical AND.

Description: $GPR[rd] \leftarrow GPR[rs] \text{ AND } GPR[rt]$

The contents of GPR *rs* are combined with the contents of GPR *rt* in a bitwise logical AND operation. The result is placed into GPR *rd*.

Restrictions:

None

Operation:

$GPR[rd] \leftarrow GPR[rs] \text{ and } GPR[rt]$

Exceptions:

None

Format: ANDI *rt*, *rs*, *immediate*

MIPS32

Purpose: And Immediate

To do a bitwise logical AND with a constant

Description: $GPR[rt] \leftarrow GPR[rs] \text{ AND } immediate$

The 16-bit immediate is zero-extended to the left and combined with the contents of GPR *rs* in a bitwise logical AND operation. The result is placed into GPR *rt*.

Restrictions:

None

Operation:

$GPR[rt] \leftarrow GPR[rs] \text{ and } zero_extend(immediate)$

Exceptions:

None

Format: AUI

AUI

AUI rt, rs immediate

MIPS32 Release 6

Purpose: Add Immediate to Upper Bits

Add Upper Immediate

Description:

AUI: $GPR[rt] \leftarrow GPR[rs] + (immediate \ll 16)$

AUI: The 16 bit immediate is shifted left 16 bits, sign-extended, and added to the register *rs*, storing the result in *rt*.

Restrictions:

Availability and Compatibility:

AUI is introduced by and required as of Release 6.

Operation:

AUI: $GPR[rt] \leftarrow GPR[rs] + (immediate \ll 16)$

Exceptions:

None.

In Release 6, LUI is an assembly idiom for AUI with *rs*=0.

Programming Notes:

AUI can be used to synthesize large constants in situations where it is not convenient to load a large constant from memory. To simplify hardware that may recognize sequences of instructions as generating large constants, AUI should be used in a stylized manner.

To create an integer:

```
LUI rd, imm_low
ORI rd, rd, imm_upper
```

To create a large offset for a memory access whose address is of the form *rbase*+*large_offset*:

```
AUI rtmp, rbase, imm_upper
LW rd, (rtmp)imm_low
```

To create a large constant operand for an instruction of the form *rd*:=*rs*+*large_immediate* or *rd*:=*rs*-*large_immediate*:

```
AUI rtmp, rs, imm_upper
ADDUI rd, rtmp, imm_low
```

For other instructions with large constant operands non-additive instructions (such as logical operators AND/OR/XOR, indirect branches, so on), no idioms are recommended apart from those to create a large constant.

Independent instructions may be interleaved between the instructions in the recommended instruction sequences.

Format: AUIPC rs, immediate

MIPS32 Release 6

Purpose: Add Upper Immediate to PC

Description: $GPR[rs] \leftarrow (PC + (immediate \ll 16))$

This instruction performs a PC-relative address calculation. The 16-bit immediate is shifted left by 16 bits, sign-extended, and added to the address of the AUIPC instruction. The result is placed in GPR *rs*.

Restrictions:

None

Availability and Compatibility:

This instruction is introduced by and required as of Release 6.

Operation:

$GPR[rs] \leftarrow (PC + (immediate \ll 16))$

Exceptions:

None

Format: B offset

Assembly Idiom

Purpose: Unconditional Branch

To do an unconditional branch.

Description: branch

B offset is the assembly idiom used to denote an unconditional branch. The actual instruction is interpreted by the hardware as BEQ r0, r0, offset.

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

Restrictions:

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See [4.1.3 “Jump and Branch Instructions” on page 86](#) in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Operation:

I: target_offset \leftarrow sign_extend(offset || 0²)
I+1: PC \leftarrow PC + target_offset

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 Kbytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

pre-Release 6:

Release 6:

Format: BAL offset

Assembly Idiom MIPS32, MIPS32 Release 6

Purpose: Branch and Link

To do an unconditional PC-relative procedure call.

Description: `procedure_call`

Place the return address link in GPR 31. The return link is the address of the second instruction following the branch, where execution continues after a procedure call.

An 18-bit signed offset (the 16-bit *offset* field shifted left 2-bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

Restrictions:

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Availability and Compatibility:

Pre-Release 6: BAL offset is the assembly idiom used to denote an unconditional branch. The actual instruction is interpreted by the hardware as BGEZAL r0, offset.

Release 6 keeps the BAL special case of BGEZAL, but removes all other instances of BGEZAL. BGEZAL with *rs* any register other than GPR [0] is required to signal a Reserved Instruction exception.

Operation:

```

I:      target_offset ← sign_extend(offset || 02)
          GPR[31] ← PC + 8
I+1:    PC ← PC + target_offset
  
```

Exceptions:

None

Programming Notes:

BAL without a corresponding return should NOT be used to read the PC. Doing so is likely to cause a performance

loss on processors with a return address predictor.

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump and link (JAL) or jump and link register (JALR) instructions for procedure calls to addresses outside this range.

Format: BALC offset

MIPS32 Release 6

Purpose: Branch and Link, Compact

To do an unconditional PC-relative procedure call.

Description: `procedure_call` (no delay slot)

Place the return address link in GPR 31. The return link is the address of the instruction immediately following the branch, where execution continues after a procedure call. (Since compact branches have no delay slots, see below.)

The branch target is formed by sign extending the 26-bit offset field of the instruction shifted left by 2 bits (since MIPS instructions are 4 byte aligned), and adding it to the PC of the following instruction, that is, adding it to the PC of the current instruction + the instruction length, PC+4.¹

Compact branches have no delay slot: the instruction after the branch is NOT executed if the branch is taken.

Restrictions:

This instruction is an unconditional, always taken, compact branch, and hence does not have a Forbidden Slot.

Availability and Compatibility:

This instruction is introduced by and required as of Release 6.

Release 6 instruction BALC occupies the same encoding as pre-Release 6 instruction SWC2. The SWC2 instruction is removed in Release 6.²

Exceptions:

None³

Operation:

```
target_offset ← sign_extend( offset || 02 )
GPR[31] ← PC+4
PC ← PC+4 + sign_extend(target_offset)
```

1. In this instruction description, PC refers to the PC of the current instruction. In some older instruction descriptions, PC is used inconsistently, often in association with the I: / I+1: notation related to delayed branches. That is in Pre-Release 6 branch (B) PC refers to the address of the next instruction, but in branch and link (BAL) it refers to the address of the current instruction.
2. Release 6 changes the encoding of instructions such as LWC2, SWC2, LDC2, and SDC2: for example, the pre-Release 6 encoding SWC2 111010.base.rt.offset16 is removed, and Release 6 encoding SWC2 010010.01011.rt.base.disp11 is added. Similarly for LWC2, SDC2, and LDC2.
3. Except for possible Reserved Instruction Exception if used in a Forbidden Slot, true of these and most other control transfer instructions (CTIs)

Format: BC offset

MIPS32 Release 6

Purpose: Branch, Compact

Description: $PC \leftarrow PC+4 + \text{sign_extend}(\text{offset} \ll 2)$

The branch target is formed by sign extending the 26-bit offset field of the instruction shifted left by 2 bits (since MIPS instructions are 4 byte aligned), and adding it to the PC of the following instruction, such as adding it to the PC of the current instruction + the instruction length, PC+4.¹

Compact branches have no delay slot: the instruction after the branch is NOT executed if the branch is taken.

Restrictions:

This instruction is an unconditional, always taken, compact branch. It does not have a Forbidden Slot.

Availability and Compatibility:

This instruction is introduced by and required as of Release 6.

Release 6 instruction BC occupies the same encoding as pre-Release 6 instruction LWC2. The instruction LWC2 is removed in Release 6.²

Exceptions:

None³

Operation:

$$\begin{aligned} \text{target_offset} &\leftarrow \text{sign_extend}(\text{offset} \mid\mid 0^2) \\ PC &\leftarrow (PC+4 + \text{sign_extend}(\text{target_offset})) \end{aligned}$$

-
1. In this instruction description, PC refers to the PC of the current instruction. In some older instruction descriptions, PC is used inconsistently, often in association with the I: / I+1: notation related to delayed branches. For example, in pre-Release 6 branch (B) PC refers to the address of the next instruction, but in branch and link (BAL) it refers to the address of the current instruction.
 2. Release 6 changes the encoding of instructions such as LWC2, SWC2, LDC2, and SDC2: for example, the pre-Release 6 encoding SWC2 111010.base.rt.offset16 is removed, and Release 6 encoding SWC2 010010.01011.rt.base.disp11 is added. Similarly for LWC2, SDC2, and LDC2.
 3. Except for possible Reserved Instruction Exception if used in a Forbidden Slot, true of these and most other control transfer instructions (CTIs)

31	26	25	21	20	16	15	0
COP1 010001	BC1EQZ 01001	ft	offset				
COP1 010001	BC1NEZ 01101	ft	offset				
6	5	5	16				

Format: BC1EQZ BC1NEZ
 BC1EQZ ft, offset
 BC1NEZ ft, offset

MIPS32 Release 6
MIPS32 Release 6

Purpose: Branch if Coprocessor 1 (FPU) Register Bit 0 Equal/Not Equal to Zero

BC1EQZ: Branch if Coprocessor 1 (FPU) Register Bit 0 is Equal to Zero

BC1NEZ: Branch if Coprocessor 1 (FPR) Register Bit 0 is Not Equal to Zero

Description:

BC1EQZ: if FPR[ft].bit0 = 0 then branch
 BC1NEZ: if FPR[ft].bit0 ≠ 0 then branch

The condition is evaluated on FPU register *ft*.

- For BC1EQZ, the condition is true if and only if bit 0 of the FPU register *ft* is zero.
- For BC1NEZ, the condition is true if and only if bit 0 of the FPU register *ft* is non-zero.

If the condition is false, the branch is not taken, and execution continues with the next instruction.

If the condition is true, the instruction in the branch delay slot is executed, and the branch is taken.

The branch target is formed by sign extending the 16-bit offset field of the instruction shifted left by 2 bits (since MIPS instructions are 4 byte aligned), and adding it to the PC of the following instruction, that is adding it to the PC of the current instruction + the instruction length, PC+4¹.

Restrictions:

If access to Coprocessor 1 is not enabled, a Coprocessor Unusable Exception is signaled.

Because these instructions BC1EQZ and BC1NEZ do not depend on a particular floating point data type, they operate whenever Coprocessor 1 is enabled.

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See [4.1.3 “Jump and Branch Instructions” on page 86](#) in Volume I for detailed discussion of correctness and performance issues.

If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Availability and Compatibility:

These instructions are introduced by and required as of Release 6.

1. In this instruction description, PC refers to the PC of the current instruction. In some older instruction descriptions, PC is used inconsistently, often in association with the I: / I+1: notation related to delayed branches. For example, in Pre-Release 6 branch (B) PC refers to the address of the next instruction, but in branch and link (BAL) it refers to the address of the current instruction.

Exceptions:Coprocessor Unusable²**Operation:**

```

tmp ← ValueFPR(ft, UNINTERPRETED_WORD)
BC1EQZ: cond ← tmp.bit0 = 0
BC1NEZ: cond ← tmp.bit0 ≠ 0
if cond then
    I:    target_PC ← ( PC+4 + sign_extend( offset << 2 )
    I+1:  PC ← target_PC

```

Programming Notes:

Release 6: These instructions, BC1EQZ and BC1NEZ, replace the pre-Release 6 instructions BC1F and BC1T. These Release 6 FPU branches depend on bit 0 of the scalar FPU register.

Note: BC1EQZ and BC1NEZ do not have a format or data type width. The same instructions are used for branches based on conditions involving any format, including 32-bit S (single precision) and W (word) format, and 64-bit D (double precision) and L (longword) format, as well as 128-bit MSA. The FPU scalar comparison instruction CMP.condn.fmt produces a mask of the same width as its format. For example, CMP.condn.S produces a 32-bit mask, with the upper 32-bits UNPREDICTABLE. Nevertheless, BC1EQZ and BC1NEZ, considering only bit 0, operate as expected. That is, CMP.condn.fmt produces an allZeroes/allOnes truth mask of its format width, whereas the BC1* branches consume bit 0 only. Similarly for CLASS.fmt.

-
2. In Release 6, BC1EQZ and BC1NEZ are required, if the FPU is implemented. They must not signal a Reserved Instruction Exception. They can signal a Coprocessor Unusable Exception.

31	26	25	21	20	18	17	16	15	0
COP1 010001		BC 01000		cc	nd 0	tf 0	offset		
6		5		3	1	1	16		

Format: BC1F offset (cc = 0 implied)
BC1F cc, offset

MIPS32, removed in Release 6
MIPS32, removed in Release 6

Purpose: Branch on FP False

To test an FP condition code and do a PC-relative conditional branch.

Description: if FPConditionCode(cc) = 0 then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself) in the branch delay slot to form a PC-relative effective target address. If the FP condition code bit *cc* is false (0), the program branches to the effective target address after the instruction in the delay slot is executed. An FP condition code is set by the FP compare instruction, C.cond.fmt.

Restrictions:

Control Transfer Instructions (CTIs) should not be placed in branch delay slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:    condition ← FPConditionCode(cc) = 0
        target_offset ← (offset15)GPRLen-(16+2) || offset || 02
I+1:  if condition then
        PC ← PC + target_offset
    endif

```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

This instruction has been removed in Release 6 and has been replaced by the ‘branch on condition 1 equal to zero’ instruction. Refer to the ‘BC1EQZ’ instruction in this manual for more information.

Historical Information:

The MIPS I architecture defines a single floating point condition code, implemented as the coprocessor 1 condition

signal (*Cp1Cond*) and the *C* bit in the FP *Control/Status* register. MIPS I, II, and III architectures must have the *CC* field set to 0, which is implied by the first format in the “Format” section.

The MIPS IV and MIPS32 architectures add seven more *Condition Code* bits to the original condition code 0. FP compare and conditional branch instructions specify the *Condition Code* bit to set or test. Both assembler formats are valid for MIPS IV and MIPS32.

In the MIPS I, II, and III architectures there must be at least one instruction between the compare instruction that sets the condition code and the branch instruction that tests it. Hardware does not detect a violation of this restriction.

Format: BC1FL offset (cc = 0 implied)
BC1FL cc, offset

MIPS32, removed in Release 6
MIPS32, removed in Release 6

Purpose: Branch on FP False Likely

To test an FP condition code and make a PC-relative conditional branch; execute the instruction in the delay slot only if the branch is taken.

Description: if FPConditionCode(cc) = 0 then branch_likely

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself) in the branch delay slot to form a PC-relative effective target address. If the FP *Condition Code* bit *cc* is false (0), the program branches to the effective target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

An FP condition code is set by the FP compare instruction, C.cond.fmt.

Restrictions:

The Branch Likely instructions have been removed from the MIPS32 Release 6.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

This operation specification is for the general Branch On Condition operation with the *tf* (true/false) and *nd* (nullify delay slot) fields as variables. The individual instructions BC1F, BC1FL, BC1T, and BC1TL have specific values for *tf* and *nd*.

```

I:      condition ← FPConditionCode(cc) = 0
          target_offset ← (offset15)GPRLEN-(16+2) || offset || 02
I+1:    if condition then
              PC ← PC + target_offset
          else
              NullifyCurrentInstruction()
          endif

```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is

encouraged to use the BC1F instruction instead.

Historical Information:

The MIPS I architecture defines a single floating point condition code, implemented as the coprocessor 1 condition signal (*Cp1Cond*) and the *C* bit in the FP *Control/Status* register. MIPS I, II, and III architectures must have the *CC* field set to 0, which is implied by the first format in the “Format” section.

The MIPS IV and MIPS32 architectures add seven more *Condition Code* bits to the original condition code 0. FP compare and conditional branch instructions specify the *Condition Code* bit to set or test. Both assembler formats are valid for MIPS IV and MIPS32.

In the MIPS II and III architectures, there must be at least one instruction between the compare instruction that sets a condition code and the branch instruction that tests it. Hardware does not detect a violation of this restriction.

Format: BC1T offset (cc = 0 implied)
BC1T cc, offset

MIPS32, removed in Release 6
MIPS32, removed in Release 6

Purpose: Branch on FP True

To test an FP condition code and do a PC-relative conditional branch.

Description: if FPConditionCode(cc) = 1 then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself) in the branch delay slot to form a PC-relative effective target address. If the FP condition code bit *cc* is true (1), the program branches to the effective target address after the instruction in the delay slot is executed. An FP condition code is set by the FP compare instruction, C.cond.fmt.

Restrictions:

Control Transfer Instructions (CTIs) should not be placed in branch delay slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:    condition ← FPConditionCode(cc) = 1
        target_offset ← (offset15)GPRLEN-(16+2) || offset || 02
I+1:  if condition then
        PC ← PC + target_offset
    endif

```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

This instruction has been replaced by the ‘branch on condition 1 not equal to zero’ instruction. Refer to the ‘BC1NEZ’ instruction in this manual for more information.

Historical Information:

The MIPS I architecture defines a single floating point condition code, implemented as the coprocessor 1 condition

signal (*Cp1Cond*) and the *C* bit in the FP *Control/Status* register. MIPS I, II, and III architectures must have the *CC* field set to 0, which is implied by the first format in the “Format” section.

The MIPS IV and MIPS32 architectures add seven more *Condition Code* bits to the original condition code 0. FP compare and conditional branch instructions specify the *Condition Code* bit to set or test. Both assembler formats are valid for MIPS IV and MIPS32.

Unimplemented Operation

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch

will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BC1T instruction instead.

Historical Information:

The MIPS I architecture defines a single floating point condition code, implemented as the coprocessor 1 condition signal (*Cp1Cond*) and the *C* bit in the FP *Control/Status* register. MIPS I, II, and III architectures must have the *CC* field set to 0, which is implied by the first format in the “Format” section.

The MIPS IV and MIPS32 architectures add seven more *Condition Code* bits to the original condition code 0. FP compare and conditional branch instructions specify the *Condition Code* bit to set or test. Both assembler formats are valid for MIPS IV and MIPS32.

In the MIPS II and III architectures, there must be at least one instruction between the compare instruction that sets a condition code and the branch instruction that tests it. Hardware does not detect a violation of this restriction.

31	26	25	21	20	16	15	0
COP2 010010	BC2EQZ 01001	ct	offset				
COP2 010010	BC2NEZ 01101	ct	offset				
6	5	5	16				

Format: BC2EQZ BC2NEZ
 BC2EQZ ct, offset
 BC2NEZ ct, offset

MIPS32 Release 6
MIPS32 Release 6

Purpose: Branch if Coprocessor 2 Condition (Register) Equal/Not Equal to Zero

BC2EQZ: Branch if Coprocessor 2 Condition (Register) is Equal to Zero

BC2NEZ: Branch if Coprocessor 2 Condition (Register) is Not Equal to Zero

Description:

BC2EQZ: if COP2Condition[ct] = 0 then branch
 BC2NEZ: if COP2Condition[ct] ≠ 0 then branch

The 5-bit field ct specifies a coprocessor 2 condition.

- For BC2EQZ if the coprocessor 2 condition is true the branch is taken.
- For BC2NEZ if the coprocessor 2 condition is false the branch is taken.

BC2EQZ and BC2NEZ have branch delay slots.

The branch target is formed by sign extending the 16-bit offset field of the instruction shifted left by 2 bits (since MIPS instructions are 4 byte aligned), and adding it to the PC of the following instruction, i.e. adding it to the PC of the current instruction + the instruction length, PC+4¹

Restrictions:

If access to Coprocessor 2 is not enabled, a Coprocessor Unusable Exception is signaled.

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Availability and Compatibility:

These instructions are introduced by and required as of Release 6.

-
- In this instruction description, PC refers to the PC of the current instruction. In some older instruction descriptions, PC is used inconsistently, often in association with the I / I+1: notation related to delayed branches. For example, in the pre-Release 6 branch instruction (B) PC refers to the address of the next instruction, but in branch and link (BAL) it refers to the address of the current instruction.

Exceptions:

Coprocessor Unusable, Reserved Instruction

Operation:

```
tmpcond ← Coprocessor2Condition(ct)
if BC2NEZ then
    tmpcond ← not(tmpcond)
endif

if tmpcond then
    PC ← PC+4 + sign_extend( immediate << 2 )
endif
```

Implementation Notes:

As of Release 6 these instructions, BC2EQZ and BC2NEZ, replace the pre-Release 6 instructions BC2F and BC2T, which had a 3-bit condition code field (as well as nullify and true/false bits).

Release 6 makes all 5 bits of the `ct` condition code available to the coprocessor designer as a condition specifier.

A customer defined coprocessor instruction set can implement any sort of condition it wants. For example, it could implement up to 32 single-bit flags, specified by the 5-bit field `ct`. It could also implement conditions encoded as values in a coprocessor register (such as testing the least significant bit of a coprocessor register) as done by Release 6 coprocessor 1, the FPU, instructions BC1EQZ/BC1/NEZ.

31	26	25	21	20	18	17	16	15	0
COP2 010010		BC 01000		cc	nd 0	tf 0	offset		
6		5		3	1	1	16		

Format: BC2F offset (cc = 0 implied)
BC2F cc, offset

MIPS32, removed in Release 6
MIPS32, removed in Release 6

Purpose: Branch on COP2 False

To test a COP2 condition code and do a PC-relative conditional branch.

Description: if COP2Condition(cc) = 0 then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself) in the branch delay slot to form a PC-relative effective target address. If the COP2 condition specified by *cc* is false (0), the program branches to the effective target address after the instruction in the delay slot is executed.

Restrictions:

Control Transfer Instructions (CTIs) should not be placed in branch delay slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:    condition ← COP2Condition(cc) = 0
        target_offset ← (offset15)GPRLen-(16+2) || offset || 02
I+1:  if condition then
        PC ← PC + target_offset
        endif

```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

This instruction has been replaced by the ‘branch on condition 2 equal to zero’ instruction. Refer to the ‘BC2EQZ’ instruction in this manual for more information.

Format: BC2FL offset (cc = 0 implied)
BC2FL cc, offset

MIPS32, removed in Release 6
MIPS32, removed in Release 6

Purpose: Branch on COP2 False Likely

To test a COP2 condition code and make a PC-relative conditional branch; execute the instruction in the delay slot only if the branch is taken.

Description: if COP2Condition(cc) = 0 then branch_likely

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself) in the branch delay slot to form a PC-relative effective target address. If the COP2 condition specified by *cc* is false (0), the program branches to the effective target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

Restrictions:

The Branch Likely instructions have been removed from the MIPS32 Release 6.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

This operation specification is for the general Branch On Condition operation with the *tf* (true/false) and *nd* (nullify delay slot) fields as variables. The individual instructions BC2F, BC2FL, BC2T, and BC2TL have specific values for *tf* and *nd*.

```

I:      condition ← COP2Condition(cc) = 0
          target_offset ← (offset15)GPRLLEN-(16+2) || offset || 02
I+1:    if condition then
              PC ← PC + target_offset
          else
              NullifyCurrentInstruction()
          endif

```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BC2F instruction instead.

6		5		3	1	1	16		

Format: BC2T offset (cc = 0 implied)
BC2T cc, offset

MIPS32, removed in Release 6
MIPS32, removed in Release 6

Purpose: Branch on COP2 True

To test a COP2 condition code and do a PC-relative conditional branch.

Description: if COP2Condition(cc) = 1 then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself) in the branch delay slot to form a PC-relative effective target address. If the COP2 condition specified by *cc* is true (1), the program branches to the effective target address after the instruction in the delay slot is executed.

Restrictions:

Control Transfer Instructions (CTIs) should not be placed in branch delay slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:    condition ← COP2Condition(cc) = 1
        target_offset ← (offset15)GPRLLEN-(16+2) || offset || 02
I+1:  if condition then
        PC ← PC + target_offset
        endif

```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

This instruction has been replaced by the ‘branch on condition 2 not equal to zero’ instruction. Refer to the ‘BC2NEZ’ instruction in this manual for more information.

Format: BC2TL offset (cc = 0 implied)
BC2TL cc, offset

MIPS32, removed in Release 6
MIPS32, removed in Release 6

Purpose: Branch on COP2 True Likely

To test a COP2 condition code and do a PC-relative conditional branch; execute the instruction in the delay slot only if the branch is taken.

Description: if COP2Condition(cc) = 1 then branch_likely

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself) in the branch delay slot to form a PC-relative effective target address. If the COP2 condition specified by *cc* is true (1), the program branches to the effective target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

Restrictions:

The Branch Likely instructions have been removed from the MIPS32 Release 6.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

This operation specification is for the general Branch On Condition operation with the *tf* (true/false) and *nd* (nullify delay slot) fields as variables. The individual instructions BC2F, BC2FL, BC2T, and BC2TL have specific values for *tf* and *nd*.

```

I:      condition ← COP2Condition(cc) = 1

I+1:    if condition then
              PC ← PC + target_offset
          else
              NullifyCurrentInstruction()
          endif

```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BC2T instruction instead.

Format: BEQ *rs*, *rt*, *offset*

MIPS32

Purpose: Branch on Equal

To compare GPRs then do a PC-relative conditional branch.

Description: if GPR[*rs*] = GPR[*rt*] then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* and GPR *rt* are equal, branch to the effective target address after the instruction in the delay slot is executed.

Restrictions:

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See [4.1.3 “Jump and Branch Instructions” on page 86](#) in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ← (GPR[rs] = GPR[rt])
I+1:  if condition then
        PC ← PC + target_offset
      endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

BEQ *r0*, *r0* *offset*, expressed as B *offset*, is the assembly idiom used to denote an unconditional branch.

Format: BEQL rs, rt, offset

MIPS32, removed in Release 6

Purpose: Branch on Equal Likely

To compare GPRs then do a PC-relative conditional branch; execute the delay slot only if the branch is taken.

Description: if GPR[rs] = GPR[rt] then branch_likely

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* and GPR *rt* are equal, branch to the target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

Restrictions:

The Branch Likely instructions have been removed from the MIPS32 Release 6.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:      target_offset ← sign_extend(offset || 02)
          condition ← (GPR[rs] = GPR[rt])
I+1:    if condition then
            PC ← PC + target_offset
          else
            NullifyCurrentInstruction()
          endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BEQ instruction instead.

Historical Information:

In the MIPS I architecture, this instruction signaled a Reserved Instruction Exception.

Format: BGEZ *rs*, *offset*

MIPS32

Purpose: Branch on Greater Than or Equal to Zero

To test a GPR then do a PC-relative conditional branch

Description: if $GPR[rs] \geq 0$ then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are greater than or equal to zero (sign bit is 0), branch to the effective target address after the instruction in the delay slot is executed.

Restrictions:

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See [4.1.3 “Jump and Branch Instructions” on page 86](#) in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ←  $GPR[rs] \geq 0^{GPRLEN}$ 
I+1:  if condition then
        PC ← PC + target_offset
      endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Format: BGEZAL *rs*, *offset*

MIPS32, removed in Release 6

Purpose: Branch on Greater Than or Equal to Zero and Link

To test a GPR then do a PC-relative conditional procedure call

Description: if GPR[*rs*] ≥ 0 then *procedure_call*

Place the return address link in GPR 31. The return link is the address of the second instruction following the branch, where execution continues after a procedure call.

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are greater than or equal to zero (sign bit is 0), branch to the effective target address after the instruction in the delay slot is executed.

Availability and Compatibility

This instruction has been removed in Release 6 with the exception of special case BAL (unconditional Branch and Link) which was an alias for BGEZAL with *rs*=0.

Restrictions:

Control Transfer Instructions (CTIs) should not be placed in branch delay slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Branch-and-link Restartability: GPR 31 must not be used for the source register *rs*, because such an instruction does not have the same effect when reexecuted. The result of executing such an instruction is **UNPREDICTABLE**. This restriction permits an exception handler to resume execution by reexecuting the branch when an exception occurs in the branch delay slot or forbidden slot.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ← GPR[rs] ≥ 0GPRLEN
        GPR[31] ← PC + 8
I+1:  if condition then
        PC ← PC + target_offset
    endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump and link (JAL) or jump and link register (JALR) instructions for procedure calls to addresses outside this range.

BGEZAL *r0*, *offset*, expressed as BAL *offset*, is the assembly idiom used to denote a PC-relative branch and link.

BAL is used in a manner similar to JAL, but provides PC-relative addressing and a more limited target PC range.

31	26	25	21	20	16	15	0
POP06 000110	BLEZALC 00000 rt ≠ 00000					offset

BGEZALC rt, offset

BGTZALC rt, offset

BLTZALC rt, offset

BEQZALC rt, offset

BNEZALC rt, offset

MIPS32 Release 6

MIPS32 Release 6

MIPS32 Release 6

MIPS32 Release 6

MIPS32 Release 6

MIPS32 Release 6

Purpose: Compact zero-compare and branch-and-link instructions

BLEZALC: Compact branch-and-link if GPR rt is less than or equal to zero

BGEZALC: Compact branch-and-link if GPR rt is greater than or equal to zero

BGTZALC: Compact branch-and-link if GPR rt is greater than zero

BLTZALC: Compact branch-and-link if GPR rt is less than to zero

BEQZALC: Compact branch-and-link if GPR rt is equal to zero

BNEZALC: Compact branch-and-link if GPR rt is not equal to zero

Description: if condition(GPR[rt]) then procedure_call branch (no delay slot)

The condition is evaluated. If the condition is true, the branch is taken.

Places the return address link in GPR 31. The return link is the address of the instruction immediately following the branch, where execution continues after a procedure call. (Compact branch-and-links such as these have no delay

slots, see below.)

The return address link is unconditionally updated.

The branch target is formed by sign extending the 16-bit offset field of the instruction shifted left by 2 bits (since MIPS instructions are 4 byte aligned), and adding it to the PC of the following instruction, i.e. adding it to the PC of the current instruction + the instruction length, PC+4.¹

BLEZALC: the condition is true if and only if GPR *rt* is less than or equal to zero.

BGEZALC: the condition is true if and only if GPR *rt* is greater than or equal to zero.

BLTZALC: the condition is true if and only if GPR *rt* is less than zero.

BGTZALC: the condition is true if and only if GPR *rt* is greater than zero.

BEQZALC: the condition is true if and only if GPR *rt* is equal to zero.

BNEZALC: the condition is true if and only if GPR *rt* is not equal to zero.

Restrictions:

Compact branches such as these have no delay slot: the instruction after the branch is NOT executed if the branch is taken, but only if the branch is not-taken. The instruction after the branch is in the Forbidden Slot.

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Release 6: If a control transfer instruction (CTI) is placed in the forbidden slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Availability and Compatibility:

These instructions are introduced by and required as of Release 6.

- BEQZALC reuses the opcode assigned to pre-Release 6 ADDI.
- BNEZALC reuses the opcode assigned to pre-Release 6 MIPS64 DADDI.

These instructions occupy primary opcode spaces originally allocated to other instructions. BLEZALC and BGEZALC have the same primary opcode as BLEZ, and are distinguished by *rs* and *rt* register numbers. Similarly, BGTZALC and BLTZALC have the same primary opcode as BGTZ, and are distinguished by register fields. BEQZALC and BNEZALC reuse the primary opcodes ADDI and DADDI.

Exceptions:

None²

Operation:

```
GPR[31] ← PC+4
target_offset ← sign_extend( offset || 02 )

BLTZALC: cond ← GPR[rt] < 0
```

1. In this instruction description, PC refers to the PC of the current instruction. In some older instruction descriptions, PC is used inconsistently, often in association with the I: / I+1: notation related to delayed branches. For example, in Pre-Release 6 branch (B) PC refers to the address of the next instruction, but in branch and link (BAL) it refers to the address of the current instruction.
2. Except for possible Reserved Instruction Exception if used in a Forbidden Slot, true of these and most other control transfer instructions (CTIs)

```

BLEZALC: cond ← GPR[rt] ≤ 0
BGEZALC: cond ← GPR[rt] ≥ 0
BGTZALC: cond ← GPR[rt] > 0
BEQZALC: cond ← GPR[rt] = 0
BNEZALC: cond ← GPR[rt] ≠ 0

if cond then
    PC ← ( PC+4+ sign_extend( target_offset ) )
endif

```

Programming Notes:

Software that performs incomplete instruction decode may incorrectly decode these new instructions, because of their very tight encoding. For example, a disassembler might look only at the primary opcode field, instruction bits 31-26, to decode BLEZL 010110.rs.00000.offset16, without checking that the “rt” field is zero. Such software violated the pre-Release 6 architecture specification.

With the 16-bit offset shifted left 2 bits and sign extended, the conditional branch range is ± 128 KBytes. Other instructions such as pre-Release 6 JAL and JALR, or Release 6 JIALC and BALC have larger ranges. In particular, BALC, with a 26-bit offset shifted by 2 bits, has a 28-bit range, ± 128 MBytes. Code sequences using AUIPC and JIALC allow still greater PC-relative range.

Format: BGEZALL *rs*, *offset*

MIPS32, removed in Release 6

Purpose: Branch on Greater Than or Equal to Zero and Link Likely

To test a GPR then do a PC-relative conditional procedure call; execute the delay slot only if the branch is taken.

Description: if $\text{GPR}[\text{rs}] \geq 0$ then *procedure_call_likely*

Place the return address link in GPR 31. The return link is the address of the second instruction following the branch, where execution continues after a procedure call.

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are greater than or equal to zero (sign bit is 0), branch to the effective target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

Restrictions:

Control Transfer Instructions (CTIs) should not be placed in branch delay slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Branch-and-link Restartability: GPR 31 must not be used for the source register *rs*, because such an instruction does not have the same effect when reexecuted. The result of executing such an instruction is **UNPREDICTABLE**. This restriction permits an exception handler to resume execution by reexecuting the branch when an exception occurs in the branch delay slot.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ←  $\text{GPR}[\text{rs}] \geq 0^{\text{GPRLEN}}$ 
        GPR[31] ← PC + 8
I+1:  if condition then
        PC ← PC + target_offset
        else
        NullifyCurrentInstruction()
        endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump and link (JAL) or jump and link register (JALR) instructions for procedure calls to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BGEZAL instruction instead.

Historical Information:

In the MIPS I architecture, this instruction signaled a Reserved Instruction Exception.

Format: B<cond>C rs,rt, offset

MIPS32 Release 6

Purpose: Compact compare-and-branch instructions

Format Details:

Equal/Not-Equal register-register compare and branch with 16-bit offset:

BEQC *rs,rt, offset*
BNEC *rs,rt, offset*

MIPS32 Release 6

MIPS32 Release 6

Signed register-register compare and branch with 16-bit offset:

BLTC *rs,rt, offset*
BGEC *rs,rt, offset*

MIPS32 Release 6

MIPS32 Release 6

Unsigned register-register compare and branch with 16-bit offset:

BLTUC *rs,rt, offset*
BGEUC *rs,rt, offset*

MIPS32 Release 6

MIPS32 Release 6

Assembly idioms with reversed operands for signed/unsigned compare-and-branch:

BGTC *rt,rs, offset*
BLEC *rt,rs, offset*
BGTUC *rt,rs, offset*
BLEUC *rt,rs, offset*

Assembly Idiom

Assembly Idiom

Assembly Idiom

Assembly Idiom

Signed Compare register to Zero and branch with 16-bit offset:

BLTZC *rt, offset*
BLEZC *rt, offset*
BGEZC *rt, offset*
BGTZC *rt, offset*

MIPS32 Release 6

MIPS32 Release 6

MIPS32 Release 6

MIPS32 Release 6

Equal/Not-equal Compare register to Zero and branch with 21-bit offset:

BEQZC *rs, offset*
BNEZC *rs, offset*

MIPS32 Release 6

MIPS32 Release 6

Description: if condition(GPR[*rs*] and/or GPR[*rt*]) then compact branch (no delay slot)

The condition is evaluated. If the condition is true, the branch is taken.

The branch target is formed by sign extending the offset field of the instruction shifted left by 2 bits (since MIPS instructions are 4 byte aligned), and adding it to the PC of the following instruction, i.e. adding it to the PC of the current instruction + the instruction length, PC+4.¹

The offset is 16 bits for most compact branches, including BLTC, BLEC, BGEC, BGTC, BNEQC, BNEC, BLTUC, BLEUC, BGEUC, BGTC, BLTZC, BLEZC, BGEZC, BGTZC. The offset is 21 bits for BEQZC and BNEZC.

Compact branches have no delay slot: the instruction after the branch is NOT executed if the branch is taken.

The instruction after the branch is defined to be the “Forbidden Slot”. If the compact branch is not taken, the instruction in the forbidden slot is executed. See below for more details.

The conditions are as follows:

Equal/Not-equal register-register compare-and-branch with 16-bit offset:

BEQC: Compact branch if GPRs are equal
BNEC: Compact branch if GPRs are not equal

Signed register-register compare and branch with 16-bit offset:

BLTC: Compact branch if GPR *rs* is less than GPR *rt*
BGEC: Compact branch if GPR *rs* is greater than or equal to GPR *rt*

1. In this instruction description, PC refers to the PC of the current instruction. In some older instruction descriptions, PC is used inconsistently, often in association with the I / I+1: notation related to delayed branches. For example, in Pre-Release 6 branch (B) PC refers to the address of the next instruction, but in branch and link (BAL) it refers to the address of the current instruction.

Unsigned register-register compare and branch with 16-bit offset:

BLTUC: Compact branch if GPR *rs* is less than GPR *rt*, unsigned

BGEUC: Compact branch if GPR *rs* is greater than or equal to GPR *rt*, unsigned

Assembly Idioms with Operands Reversed:

BLEC: Compact branch if GPR *rt* is less than or equal to GPR *rs* (alias for BGEC)

BGTC: Compact branch if GPR *rt* is greater than GPR *rs* (alias for BLTC)

BLEUC: Compact branch if GPR *rt* is less than or equal to GPR *rt*, unsigned (alias for BGEUC)

BGTUC: Compact branch if GPR *rt* is greater than GPR *rs*, unsigned (alias for BLTUC)

Compare register to zero and branch with 16-bit offset:

BLTZC: Compact branch if GPR *rt* is less than zero

BLEZC: Compact branch if GPR *rt* is less than or equal to zero

BGEZC: Compact branch if GPR *rt* is greater than or equal to zero

BGTZC: Compact branch if GPR *rt* is greater than zero

Compare register to zero and branch with 21-bit offset:

BEQZC: Compact branch if GPR *rs* is equal to zero

BNEZC: Compact branch if GPR *rs* is not equal to zero

Restrictions:

Compact branches have no delay slot: the instruction after the branch is NOT executed if the branch is taken.

The instruction after the branch is defined to be the “Forbidden Slot”. If the compact branch is not taken, the instruction in the forbidden slot is executed. See below for more details.

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See [4.1.3 “Jump and Branch Instructions” on page 86](#) in Volume I for detailed discussion of correctness and performance issues.

Release 6: If a control transfer instruction (CTI) is placed in the forbidden slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Availability and Compatibility:

These instructions are introduced by and required as of Release 6.

- BEQZC reuses the opcode assigned to pre-Release 6 LDC2.
- BNEZC reuses the opcode assigned to pre-Release 6 SDC2.
- BEQC reuses the opcode assigned to pre-Release 6 ADDI.
- BNEC reuses the opcode assigned to pre-Release 6 MIPD64 DADDI.

Exceptions:

None²

Operation:

$$\text{target_offset} \leftarrow \text{sign_extend}(\text{offset} \mid 0^2)$$

2. Except for possible Reserved Instruction Exception if used in a Forbidden Slot, true of these and most other control transfer instructions (CTIs)

```

/* Register-register compare and branch, 16 bit offset: */
/* Equal / Not-Equal */
BEQC: cond ← GPR[rs] = GPR[rt]
BNEC: cond ← GPR[rs] ≠ GPR[rt]
/* Signed */
BLTC: cond ← GPR[rs] < GPR[rt]
BGEC: cond ← GPR[rs] ≥ GPR[rt]
/* Unsigned: */
BLTUC: cond ← unsigned(GPR[rs]) < unsigned(GPR[rt])
BGEUC: cond ← unsigned(GPR[rs]) ≥ unsigned(GPR[rt])

/* Compare register to zero, small offset: */
BLTZC: cond ← GPR[rt] < 0
BLEZC: cond ← GPR[rt] ≤ 0
BGEZC: cond ← GPR[rt] ≥ 0
BGTZC: cond ← GPR[rt] > 0
/* Compare register to zero, large offset: */
BEQZC: cond ← GPR[rs] = 0
BNEZC: cond ← GPR[rs] ≠ 0

if cond then
    PC ← ( PC+4+ sign_extend( offset ) )
end if

```

Special Considerations:

See elsewhere for a complete overview of Release 6 instruction encodings. Brief notes related to compact branches such as these instructions:

In order to provide a full set of compare-and-branch instructions, Release 6 reduces some of the redundancy in instruction encoding related to the R0 register. This is indicated by constraints applied to the register encodings. For example, BGEZC *rs*, *rt* is encoded as 010110.*rs*.*rt*.*offset*16, with constraints *rs*≠00000, *rt*≠00000 and *rs*=*rt* (since BGEZ with both operands the same register is always true, hence redundant). Similarly, BEQC *rs*, *rt* has the constraints *rs*≠00000, *rt*≠00000, and *rs*<*rt* (since BEQC with both operands the same register is always true, hence redundant). Note that “*rs*” and “*rt*” in these constraints refer to register numbers as encoded within the instruction, not the values contained by the registers.

Table 3.1 below shows that the compact branches provide a full set of integer comparisons. It is necessary to reverse the operands of the signed and unsigned register-register compares in the shaded cases. Separate instructions are required for comparisons against 0, because the GPR[0] encoding is not allowed in the register-register comparisons, to save encoding space. Assembly idioms may provide the “reversed” instructions.

Table 3.1 Compact branches provide a full set of comparisons

register-register comparisons			compare to zero	
operation	signed	unsigned	instruction	operation
$a < b$	BLTC	BLTUC	BLTZC	$a < 0$
$a \leq b$	BLEC = BGEC reversed	BLEUC = BGEUC reversed	BLEZC	$a \leq 0$
$a = b$	BEQC		BEQZC	$a = 0$
$a \neq b$	BNEC		BNEZC	$a \neq 0$
$a \geq b$	BGEC	BGEUC	BGEZC	$a \geq 0$

Table 3.1 Compact branches provide a full set of comparisons

register-register comparisons			compare to zero	
operation	signed	unsigned	instruction	operation
a > b	BGTC = BLTC reversed	BGTUC = BLTUC reversed	BGTZC	a > 0

Programming Notes:

Legacy software that performs incomplete instruction decode may incorrectly decode these new instructions, because of their very tight encoding. For example, a disassembler that looks only at the primary opcode field (instruction bits 31-26) to decode BLEZL without checking that the “rt” field is zero violates the pre-Release 6 architecture specification. Complete instruction decode allows reuse of pre-Release 6 BLEZL opcode for Release 6 conditional branches.

Format: BGEZL *rs*, *offset*

MIPS32, removed in Release 6

Purpose: Branch on Greater Than or Equal to Zero Likely

To test a GPR then do a PC-relative conditional branch; execute the delay slot only if the branch is taken.

Description: if $\text{GPR}[\text{rs}] \geq 0$ then *branch_likely*

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are greater than or equal to zero (sign bit is 0), branch to the effective target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

Restrictions:

The Branch Likely instructions have been removed from the MIPS32 Release 6.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ←  $\text{GPR}[\text{rs}] \geq 0^{\text{GPRLEN}}$ 
I+1:  if condition then
        PC ← PC + target_offset
        else
        NullifyCurrentInstruction()
        endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BGEZ instruction instead.

Historical Information:

In the MIPS I architecture, this instruction signaled a Reserved Instruction Exception.

31	26	25	21	20	16	15	0
BGTZ 000111						rs	0 00000
offset							
6						5	5
						16	

Format: BGTZ *rs*, *offset*

MIPS32

Purpose: Branch on Greater Than Zero

To test a GPR then do a PC-relative conditional branch.

Description: if GPR[*rs*] > 0 then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are greater than zero (sign bit is 0 but value not zero), branch to the effective target address after the instruction in the delay slot is executed.

Restrictions:

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See [4.1.3 “Jump and Branch Instructions” on page 86](#) in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ← GPR[rs] > 0GPRLEN
I+1:  if condition then
        PC ← PC + target_offset
      endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

31	26	25	21	20	16	15	0
BGTZL 010111	rs	0 00000	offset				
6	5	5	16				

Format: BGTZL *rs*, *offset*

MIPS32, removed in Release 6

Purpose: Branch on Greater Than Zero Likely

To test a GPR then do a PC-relative conditional branch; execute the delay slot only if the branch is taken.

Description: if $GPR[rs] > 0$ then *branch_likely*

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are greater than zero (sign bit is 0 but value not zero), branch to the effective target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

Restrictions:

The Branch Likely instructions have been removed from the MIPS32 Release 6.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ←  $GPR[rs] > 0^{GPRLEN}$ 
I+1:  if condition then
        PC ← PC + target_offset
        else
        NullifyCurrentInstruction()
        endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BGTZ instruction instead.

Historical Information:

In the MIPS I architecture, this instruction signaled a Reserved Instruction Exception.

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL3 011111						00000					
rt						rd					
BITSWAP 00000						BSHFL 100000					
6						5					

Format: BITSWAP
BITSWAP rd,rt

MIPS32 Release 6

Purpose: Swaps (reverses) bits in each byte

Description: $GPR[rd].byte(i) \leftarrow reverse_bits_in_byte(GPR[rt].byte(i))$, for all bytes i

Each byte in input GPR rt is moved to the same byte position in output GPR rd , with bits in each byte reversed. BITSWAP operates on all 4 bytes of a 32-bit GPR on a 32-bit CPU.

Restrictions:

BITSWAP: None.

Availability and Compatibility:

The BITSWAP instruction is introduced by and required as of Release 6.

Operation:

```

BITSWAP:
  for i in 0 to 3 do /* for all bytes in 32-bit GPR width */
    tmp.byte(i) ← reverse_bits_in_byte( GPR[rt].byte(i) )
  endfor
  GPR[rd] ← tmp

```

where

```

function reverse_bits_in_byte(inbyte)
  outbyte7 ← inbyte0
  outbyte6 ← inbyte1
  outbyte5 ← inbyte2
  outbyte4 ← inbyte3
  outbyte3 ← inbyte4
  outbyte2 ← inbyte5
  outbyte1 ← inbyte6
  outbyte0 ← inbyte7
  return outbyte
end function

```

Exceptions:

None

Programming Notes:

The Release 6 BITSWAP instruction corresponds to the pre-Release 6 DSP Module BITREV instruction, except that the latter bit-reverses the least-significant 16-bit halfword of the input register, zero extending the rest, while BITSWAP operates on 32-bits.

Format: BLEZ rs, offset

MIPS32

Purpose: Branch on Less Than or Equal to Zero

To test a GPR then do a PC-relative conditional branch.

Description: if $GPR[rs] \leq 0$ then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are less than or equal to zero (sign bit is 1 or value is zero), branch to the effective target address after the instruction in the delay slot is executed.

Restrictions:

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See [4.1.3 “Jump and Branch Instructions” on page 86](#) in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ←  $GPR[rs] \leq 0^{GPRLEN}$ 
I+1:  if condition then
        PC ← PC + target_offset
      endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

31	26	25	21	20	16	15	0
BLEZL 010110			rs		0 00000		offset
6			5		5		16

Format: BLEZL *rs*, *offset*

MIPS32, removed in Release 6

Purpose: Branch on Less Than or Equal to Zero Likely

To test a GPR then do a PC-relative conditional branch; execute the delay slot only if the branch is taken.

Description: if $GPR[rs] \leq 0$ then *branch_likely*

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are less than or equal to zero (sign bit is 1 or value is zero), branch to the effective target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

Restrictions:

The Branch Likely instructions have been removed from the MIPS32 Release 6.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ←  $GPR[rs] \leq 0^{GPRLEN}$ 
I+1:  if condition then
        PC ← PC + target_offset
        else
        NullifyCurrentInstruction()
        endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BLEZ instruction instead.

Historical Information:

In the MIPS I architecture, this instruction signaled a Reserved Instruction Exception.

Format: BLTZ rs, offset

MIPS32

Purpose: Branch on Less Than Zero

To test a GPR then do a PC-relative conditional branch.

Description: if GPR[rs] < 0 then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are less than zero (sign bit is 1), branch to the effective target address after the instruction in the delay slot is executed.

Restrictions:

None.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:      target_offset ← sign_extend(offset || 02)
          condition ← GPR[rs] < 0GPRLEN
I+1:    if condition then
            PC ← PC + target_offset
          endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump and link (JAL) or jump and link register (JALR) instructions for procedure calls to addresses outside this range.

Format: BLTZAL rs, offset

MIPS32, removed in Release 6

Purpose: Branch on Less Than Zero and Link

To test a GPR then do a PC-relative conditional procedure call.

Description: if GPR[rs] < 0 then procedure_call

Place the return address link in GPR 31. The return link is the address of the second instruction following the branch, where execution continues after a procedure call.

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are less than zero (sign bit is 1), branch to the effective target address after the instruction in the delay slot is executed.

Availability and Compatibility:

This instruction has been removed in Release 6.

The special case BLTZAL r0, offset, has been retained as NAL in Release 6.

Restrictions:

Control Transfer Instructions (CTIs) should not be placed in branch delay slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Branch-and-link Restartability: GPR 31 must not be used for the source register *rs*, because such an instruction does not have the same effect when reexecuted. The result of executing such an instruction is **UNPREDICTABLE**. This restriction permits an exception handler to resume execution by reexecuting the branch when an exception occurs in the branch delay slot.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ← GPR[rs] < 0GPRLEN
        GPR[31] ← PC + 8
I+1:  if condition then
        PC ← PC + target_offset
    endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump and link (JAL) or jump and link register (JALR) instructions for procedure calls to addresses outside this range.

Format: BLTZALL *rs*, *offset*

MIPS32, removed in Release 6

Purpose: Branch on Less Than Zero and Link Likely

To test a GPR then do a PC-relative conditional procedure call; execute the delay slot only if the branch is taken.

Description: if $GPR[rs] < 0$ then `procedure_call_likely`

Place the return address link in GPR 31. The return link is the address of the second instruction following the branch, where execution continues after a procedure call.

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are less than zero (sign bit is 1), branch to the effective target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

Restrictions:

Control Transfer Instructions (CTIs) should not be placed in branch delay slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See [4.1.3 “Jump and Branch Instructions” on page 86](#) in Volume I for detailed discussion of correctness and performance issues.

Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Branch-and-link Restartability: GPR 31 must not be used for the source register *rs*, because such an instruction does not have the same effect when reexecuted. The result of executing such an instruction is **UNPREDICTABLE**. This restriction permits an exception handler to resume execution by reexecuting the branch when an exception occurs in the branch delay slot.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ←  $GPR[rs] < 0^{GPRLEN}$ 
        GPR[31] ← PC + 8
I+1:  if condition then
        PC ← PC + target_offset
        else
        NullifyCurrentInstruction()
        endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump and link (JAL) or jump and link register (JALR) instructions for procedure calls to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BLTZAL instruction instead.

Historical Information:

In the MIPS I architecture, this instruction signaled a Reserved Instruction Exception.

Format: BLTZL *rs*, *offset*

MIPS32, removed in Release 6

Purpose: Branch on Less Than Zero Likely

To test a GPR then do a PC-relative conditional branch; execute the delay slot only if the branch is taken.

Description: if $GPR[rs] < 0$ then *branch_likely*

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are less than zero (sign bit is 1), branch to the effective target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

Restrictions:

The Branch Likely instructions have been removed from the MIPS32 Release 6.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ←  $GPR[rs] < 0^{GPRLEN}$ 
I+1:  if condition then
        PC ← PC + target_offset
        else
        NullifyCurrentInstruction()
        endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BLTZ instruction instead.

Historical Information:

In the MIPS I architecture, this instruction signaled a Reserved Instruction Exception.

Format: BNE *rs*, *rt*, *offset*

MIPS32

Purpose: Branch on Not Equal

To compare GPRs then do a PC-relative conditional branch

Description: if $GPR[rs] \neq GPR[rt]$ then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* and GPR *rt* are not equal, branch to the effective target address after the instruction in the delay slot is executed.

Restrictions:

Control Transfer Instructions (CTIs) should not be placed in branch delay slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See [4.1.3 “Jump and Branch Instructions” on page 86](#) in Volume I for detailed discussion of correctness and performance issues.

Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ← (GPR[rs] ≠ GPR[rt])
I+1:  if condition then
        PC ← PC + target_offset
        endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Format: BNEL *rs*, *rt*, *offset*

MIPS32, removed in Release 6

Purpose: Branch on Not Equal Likely

To compare GPRs then do a PC-relative conditional branch; execute the delay slot only if the branch is taken.

Description: if $GPR[rs] \neq GPR[rt]$ then *branch_likely*

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* and GPR *rt* are not equal, branch to the effective target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

Restrictions:

The Branch Likely instructions have been removed from the MIPS32 Release 6.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

I:    target_offset ← sign_extend(offset || 02)
        condition ← (GPR[rs] ≠ GPR[rt])
I+1:  if condition then
        PC ← PC + target_offset
        else
        NullifyCurrentInstruction()
        endif

```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is ± 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BNE instruction instead.

Historical Information:

In the MIPS I architecture, this instruction signaled a Reserved Instruction Exception.

31	26	25	21	20	16	15	0
POP10 001000		BOVC rs >=rt			offset		
		rs		rt			
POP30 011000		BNVC rs>=rt			offset		
		rs		rt			
6		5		5		16	

Format: BOVC BNVC
 BOVC $rs, rt, offset$
 BNVC $rs, rt, offset$

MIPS32 Release 6
 MIPS32 Release 6

Purpose: Branch on Overflow, Compact; Branch on No Overflow, Compact

BOVC: Detect overflow for add (signed 32 bits) and branch if overflow.

BNVC: Detect overflow for add (signed 32 bits) and branch if no overflow.

Description: `branch if/if-not NotWordValue(GPR[rs]+GPR[rt])`

- BOVC performs a signed 32-bit addition of rs and rt . BOVC discards the sum, but detects signed 32-bit integer overflow of the sum, and branches if such overflow is detected.
- BNVC performs a signed 32-bit addition of rs and rt . BNVC discards the sum, but detects signed 32-bit integer overflow of the sum, and branches if such overflow is not detected.

BOVC and BNVC are compact branches—they have no branch delay slots, but do have a forbidden slot.

The branch target is formed by sign extending the 16-bit offset field of the instruction shifted left by 2 bits (since MIPS instructions are 4 byte aligned), and adding it to the PC of the following instruction, that is adding it to the PC of the current instruction + the instruction length, $PC+4$.¹

The special case with $rt=0$ (for example, $GPR[0]$) is allowed. On MIPS32, BOVC $rs, r0$ offset never branches, while BNVC $rs, r0$ offset always branches.

The special case of $rs=0$ and $rt=0$ is allowed. BOVC never branches, while BNVC always branches.

Restrictions:

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Release 6: If a control transfer instruction (CTI) is placed in the forbidden slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Availability and Compatibility:

These instructions are introduced by and required as of Release 6.

See section A.4 on page 445 in Volume II for a complete overview of Release 6 instruction encodings. Brief notes

1. In this instruction description, PC refers to the PC of the current instruction. In some older instruction descriptions, PC is used inconsistently, often in association with the $I / I+1$: notation related to delayed branches. For example, in the pre-Release 6 branch instruction (B) PC refers to the address of the next instruction, but in branch and link (BAL) it refers to the address of the current instruction.

related to these instructions:

- BOVC uses the primary opcode allocated to MIPS32 pre-Release 6 ADDI. Release 6 reuses the ADDI primary opcode for BOVC and other instructions, distinguished by register numbers.
- BNVC uses the primary opcode allocated to MIPS64 pre-Release 6 DADDI. Release 6 reuses the DADDI primary opcode for BNVC and other instructions, distinguished by register numbers.

Operation:

```
temp1 ← GPR[rs]
temp2 ← GPR[rt]
tempd ← temp1 + temp2 // wider than 32-bit precision
sum_overflow ← (tempd32 ≠ tempd31)

BOVC: cond ← sum_overflow
BNVC: cond ← not( sum_overflow )

if cond then
    PC ← ( PC+4 + sign_extend( offset << 2 ) )
endif
```

Exceptions:

None

Format:

BREAK

MIPS32

Purpose:

Breakpoint

To cause a Breakpoint exception

Description:

A breakpoint exception occurs, immediately and unconditionally transferring control to the exception handler. The *code* field is available for use as software parameters, but is retrieved by the exception handler only by loading the contents of the memory word containing the instruction.

Restrictions:

None

Operation:

SignalException(Breakpoint)

Exceptions:

Breakpoint

Purpose: Floating Point Compare

To compare FP values and record the Boolean result in a condition code.

Description: $\text{FPConditionCode}(cc) \leftarrow \text{FPR}[fs] \text{ compare_cond } \text{FPR}[ft]$

The value in FPR *fs* is compared to the value in FPR *ft*; the values are in format *fmt*. The comparison is exact and neither overflows nor underflows.

If the comparison specified by the *cond* field of the instruction is true for the operand values, the result is true; otherwise, the result is false. If no exception is taken, the result is written into condition code *CC*; true is 1 and false is 0.

In the *cond* field of the instruction: *cond*_{2..1} specify the nature of the comparison (equals, less than, and so on). *cond*₀ specifies whether the comparison is ordered or unordered, that is, false or true if any operand is a NaN; *cond*₃ indicates whether the instruction should signal an exception on QNaN inputs, or not (see [Table 3.3](#)).

C.cond.PS compares the upper and lower halves of FPR *fs* and FPR *ft* independently and writes the results into condition codes *CC* +1 and *CC* respectively. The *CC* number must be even. If the number is not even the operation of the instruction is **UNPREDICTABLE**.

If one of the values is an SNaN, or *cond*₃ is set and at least one of the values is a QNaN, an Invalid Operation condition is raised and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written and an Invalid Operation exception is taken immediately. Otherwise, the Boolean result is written into condition code *CC*.

There are four mutually exclusive ordering relations for comparing floating point values; one relation is always true and the others are false. The familiar relations are *greater than*, *less than*, and *equal*. In addition, the IEEE floating point standard defines the relation *unordered*, which is true when at least one operand value is NaN; NaN compares unordered with everything, including itself. Comparisons ignore the sign of zero, so +0 equals -0.

The comparison condition is a logical predicate, or equation, of the ordering relations such as *less than or equal*, *equal*, *not less than*, or *unordered or equal*. Compare distinguishes among the 16 comparison predicates. The Boolean result of the instruction is obtained by substituting the Boolean value of each ordering relation for the two FP values in the equation. If the *equal* relation is true, for example, then all four example predicates above yield a true result. If the *unordered* relation is true then only the final predicate, *unordered or equal*, yields a true result.

Logical negation of a compare result allows eight distinct comparisons to test for the 16 predicates as shown in [Table 3.3](#). Each mnemonic tests for both a predicate and its logical negation. For each mnemonic, *compare* tests the truth of the first predicate. When the first predicate is true, the result is true as shown in the “If Predicate Is True” column, and the second predicate must be false, and vice versa. (Note that the False predicate is never true and False/True do not follow the normal pattern.)

The truth of the second predicate is the logical negation of the instruction result. After a compare instruction, test for the truth of the first predicate can be made with the Branch on FP True (BC1T) instruction and the truth of the second

can be made with Branch on FP False (BC1F).

[Table 3.3](#) shows another set of eight compare operations, distinguished by a $cond_3$ value of 1 and testing the same 16 conditions. For these additional comparisons, if at least one of the operands is a NaN, including Quiet NaN, then an Invalid Operation condition is raised. If the Invalid Operation condition is enabled in the *FCSR*, an Invalid Operation exception occurs.

Table 3.2 FPU Comparisons Without Special Operand Exceptions

Instruction	Comparison Predicate					Comparison CC Result		Instruction	
Cond Mnemonic	Name of Predicate and Logically Negated Predicate (Abbreviation)	Relation Values				If Predicate Is True	Inv Op Excp. if QNaN?	Condition Field

	Greater Than or Equal (GE)	T	F	T	F	F			
LE	Less Than or Equal	F	T	T	F	T		6	
	Not Less Than or Equal (NLE)	T	F	F	T	F			
NGT	Not Greater Than	F	T	T	T	T		7	
	Greater Than (GT)	T	F	F	F	F			
Key: ? = unordered, > = greater than, < = less than, = is equal, T = True, F = False									

Restrictions:

The fields *fs* and *ft* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of C.cond.PS is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU,.

The result of C.cond.PS is **UNPREDICTABLE** if the condition code number is odd.

Availability and Compatibility:

This instruction has been removed in Release 6 and has been replaced by the 'CMP.cond.fmt' instruction. Refer to the CMP.cond.fmt instruction in this manual for more information. Release 6 does not support Paired Single (PS).

Operation:

```

if SNaN(ValueFPR(fs, fmt)) or SNaN(ValueFPR(ft, fmt)) or
   QNaN(ValueFPR(fs, fmt)) or QNaN(ValueFPR(ft, fmt)) then
  less ← false
  equal ← false
  unordered ← true
if (SNaN(ValueFPR(fs,fmt)) or SNaN(ValueFPR(ft,fmt))) or
   (cond3 and (QNaN(ValueFPR(fs,fmt)) or QNaN(ValueFPR(ft,fmt)))) then

```

```

        SignalException(InvalidOperation)
    endif
else
    less ← ValueFPR(fs, fmt) <_fmt ValueFPR(ft, fmt)
    equal ← ValueFPR(fs, fmt) =_fmt ValueFPR(ft, fmt)
    unordered ← false
endif
condition ← (cond2 and less) or (cond1 and equal)
            or (cond0 and unordered)
SetFPConditionCode(cc, condition)

```

For C.cond.PS, the pseudo code above is repeated for both halves of the operand registers, treating each half as an independent single-precision values. Exceptions on the two halves are logically ORed and reported together. The results of the lower half comparison are written to condition code CC; the results of the upper half comparison are written to condition code CC+1.

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation, Invalid Operation

Programming Notes:

FP computational instructions, including compare, that receive an operand value of Signaling NaN raise the Invalid Operation condition. Comparisons that raise the Invalid Operation condition for Quiet NaNs in addition to SNaNs permit a simpler programming model if NaNs are errors. Using these compares, programs do not need explicit code to check for QNaNs causing the *unordered* relation. Instead, they take an exception and allow the exception handling system to deal with the error when it occurs. For example, consider a comparison in which we want to know if two numbers are equal, but for which *unordered* would be an error.

```

# comparisons using explicit tests for QNaN
c.eq.d $f2,$f4    # check for equal
nop
bc1t  L2          # it is equal
c.un.d $f2,$f4    # it is not equal,
                  # but might be unordered
bc1t  ERROR       # unordered goes off to an error handler
# not-equal-case code here
...
# equal-case code here
L2:
# -----
# comparison using comparisons that signal QNaN
c.seq.d $f2,$f4   # check for equal
nop
bc1t  L2          # it is equal
nop
# it is not unordered here
...
# not-equal-case code here
...
# equal-case code here

```

pre-Release 6

Release 6

**Format:** CACHE op, offset(base)**MIPS32****Purpose:** Perform Cache Operation

To perform the cache operation specified by op.

Description:

The 16-bit offset is sign-extended and added to the contents of the base register to form an effective address. The effective address is used in one of the following ways based on the operation to be performed and the type of cache as described in the following table.

Table 3.4 Usage of Effective Address

Operation Requires an	Type of Cache	Usage of Effective Address
Address	Virtual	The effective address is used to address the cache. An address translation may or may not be performed on the effective address (with the possibility that a TLB Refill or TLB Invalid exception might occur)
Address	Physical	The effective address is translated by the MMU to a physical address. The physical address is then used to address the cache
Index	N/A	<p>The effective address is translated by the MMU to a physical address. It is implementation dependent whether the effective address or the translated physical address is used to index the cache. As such, an unmapped address (such as within kseg0) should always be used for cache operations that require an index. See the Programming Notes section below.</p> <p>Assuming that the total cache size in bytes is CS, the associativity is A, and the number of bytes per tag is BPT, the following calculations give the fields of the address which specify the way and the index:</p> $\begin{aligned} \text{OffsetBit} &\leftarrow \text{Log2}(\text{BPT}) \\ \text{IndexBit} &\leftarrow \text{Log2}(\text{CS} / \text{A}) \\ \text{WayBit} &\leftarrow \text{IndexBit} + \text{Ceiling}(\text{Log2}(\text{A})) \\ \text{Way} &\leftarrow \text{Addr}_{\text{WayBit}-1..\text{IndexBit}} \\ \text{Index} &\leftarrow \text{Addr}_{\text{IndexBit}-1..\text{OffsetBit}} \end{aligned}$ <p>For a direct-mapped cache, the Way calculation is ignored and the Index value fully specifies the cache tag. This is shown symbolically in the figure below.</p>

Figure 3.3 Usage of Address Fields to Select Index and Way

A TLB Refill and TLB Invalid (both with cause code equal TLBL) exception can occur on any operation. For index operations (where the address is used to index the cache but need not match the cache tag), software must use unmapped addresses to avoid TLB exceptions. This instruction never causes TLB Modified exceptions nor TLB Refill exceptions with a cause code of TLBS. This instruction never causes Execute-Inhibit nor Read-Inhibit exceptions.

The effective address may be an arbitrarily-aligned by address. The CACHE instruction never causes an Address Error Exception due to a non-aligned address.

As a result, a Cache Error exception may occur because of some operations performed by this instruction. For example, if a Writeback operation detects a cache or bus error during the processing of the operation, that error is reported via a Cache Error exception. Also, a Bus Error Exception may occur if a bus operation invoked by this instruction is terminated in an error. However, cache error exceptions must not be triggered by an Index Load Tag or Index Store tag operation, as these operations are used for initialization and diagnostic purposes.

An Address Error Exception (with cause code equal AdEL) may occur if the effective address references a portion of the kernel address space which would normally result in such an exception. It is implementation dependent whether such an exception does occur.

It is implementation dependent whether a data watch is triggered by a cache instruction whose address matches the Watch register address match conditions.

The CACHE instruction and the memory transactions which are sourced by the CACHE instruction, such as cache refill or cache writeback, obey the ordering and completion rules of the SYNC instruction.

Bits [17:16] of the instruction specify the cache on which to perform the operation, as follows:

Table 3.5 Encoding of Bits[17:16] of CACHE Instruction

Code	Name	Cache
0b00	I	Primary Instruction
0b01	D	Primary Data or Unified Primary
0b10	T	Tertiary
0b11	S	Secondary

Bits [20:18] of the instruction specify the operation to perform. To provide software with a consistent base of cache operations, certain encodings must be supported on all processors. The remaining encodings are recommended

When implementing multiple level of caches and where the hardware maintains the smaller cache as a proper subset of a larger cache (every address which is resident in the smaller cache is also resident in the larger cache; also known as the inclusion property). It is recommended that the CACHE instructions which operate on the larger, outer-level cache; must first operate on the smaller, inner-level cache. For example, a Hit_Writeback _Invalidate operation targeting the Secondary cache, must first operate on the primary data cache first. If the CACHE instruction implementation does not follow this policy then any software which flushes the caches must mimic this behavior. That is, the software sequences must first operate on the inner cache then operate on the outer cache. The software must place a SYNC instruction after the CACHE instruction whenever there are possible writebacks from the inner cache to

ensure that the writeback data is resident in the outer cache before operating on the outer cache. If neither the CACHE instruction implementation nor the software cache flush sequence follow this policy, then the inclusion property of the caches can be broken, which might be a condition that the cache management hardware cannot properly deal with.

When implementing multiple level of caches without the inclusion property, the use of a SYNC instruction after the CACHE instruction is still needed whenever writeback data has to be resident in the next level of memory hierarchy.

For multiprocessor implementations that maintain coherent caches, some of the Hit type of CACHE instruction operations may optionally affect all coherent caches within the implementation. If the effective address uses a coherent Cache Coherency Attribute (CCA), then the operation is *globalized*, meaning it is broadcast to all of the coherent caches within the system. If the effective address does not use one of the coherent CCAs, there is no broadcast of the operation. If multiple levels of caches are to be affected by one CACHE instruction, all of the affected cache levels must be processed in the same manner - either all affected cache levels use the globalized behavior or all affected cache levels use the non-globalized behavior.

Table 3.6 Encoding of Bits [20:18] of the CACHE Instruction

Code	Caches	Name	Effective Address Operand Type	Operation	Compliance Implemented
0b000	I	Index Invalidate	Index	Set the state of the cache block at the specified index to invalid. This required encoding may be used by software to invalidate the entire instruction cache by stepping through all valid indices.	Required
	D	Index Writeback Invalidate / Index Invalidate	Index	For a write-back cache: If the state of the cache block at the specified index is valid and dirty, write the block back to the memory address specified by the cache tag. After that operation is completed, set the state of the cache block to invalid. If the block is valid but not dirty, set the state of the block to invalid.	Required
	S, T	Index Writeback Invalidate / Index Invalidate	Index	For a write-through cache: Set the state of the cache block at the specified index to invalid. This required encoding may be used by software to invalidate the entire data cache by stepping through all valid indices. The Index Store Tag must be used to initialize the cache at power up.	Required if S, T cache is implemented
0b001	All	Index Load Tag	Index	Read the tag for the cache block at the specified index into the <i>TagLo</i> and <i>TagHi</i> Coprocessor 0 registers. If the <i>DataLo</i> and <i>DataHi</i> registers are implemented, also read the data corresponding to the byte index into the <i>DataLo</i> and <i>DataHi</i> registers. This operation must not cause a Cache Error Exception. The granularity and alignment of the data read into the <i>DataLo</i> and <i>DataHi</i> registers is implementation-dependent, but is typically the result of an aligned access to the cache, ignoring the appropriate low-order bits of the byte index.	Recommended

Table 3.6 Encoding of Bits [20:18] of the CACHE Instruction (Continued)

Code	Caches	Name	Effective Address Operand Type	Operation	Compliance Implemented
0b010	All	Index Store Tag	Index	Write the tag for the cache block at the specified index from the <i>TagLo</i> and <i>TagHi</i> Coprocessor 0 registers. This operation must not cause a Cache Error Exception. This required encoding may be used by software to initialize the entire instruction or data caches by stepping through all valid indices. Doing so requires that the <i>TagLo</i> and <i>TagHi</i> registers associated with the cache be initialized first.	Required
0b011	All	Implementation Dependent	Unspecified	Available for implementation-dependent operation.	Optional
0b100	I, D	Hit Invalidate	Address	If the cache block contains the specified address, set the state of the cache block to invalid. This required encoding may be used by software to invalidate a range of addresses from the instruction cache by stepping through the address range by the line size of the cache.	Required (Instruction Cache Encoding Only), Recommended otherwise
	S, T	Hit Invalidate	Address	In multiprocessor implementations with coherent caches, the operation may optionally be broadcast to all coherent caches within the system.	Optional, if Hit_Invalidate_D is implemented, the S and T variants are recommended.
0b101	I	Fill	Address	Fill the cache from the specified address.	Recommended
	D	Hit Writeback Invalidate / Hit Invalidate	Address	For a write-back cache: If the cache block contains the specified address and it is valid and dirty, write the contents back to memory. After that operation is completed, set the state of the cache block to invalid. If the block is valid but not dirty, set the state of the block to invalid.	Required
	S, T	Hit Writeback Invalidate / Hit Invalidate	Address	For a write-through cache: If the cache block contains the specified address, set the state of the cache block to invalid. This required encoding may be used by software to invalidate a range of addresses from the data cache by stepping through the address range by the line size of the cache. In multiprocessor implementations with coherent caches, the operation may optionally be broadcast to all coherent caches within the system.	Required if S, T cache is implemented

Table 3.6 Encoding of Bits [20:18] of the CACHE Instruction (Continued)

Code	Caches	Name	Effective Address Operand Type	Operation	Compliance Implemented
0b110	D	Hit Writeback	Address	<p>If the cache block contains the specified address and it is valid and dirty, write the contents back to memory. After the operation is completed, leave the state of the line valid, but clear the dirty state. For a write-through cache, this operation may be treated as a nop.</p> <p>In multiprocessor implementations with coherent caches, the operation may optionally be broadcast to all coherent caches within the system.</p>	Recommended
	S, T	Hit Writeback	Address		Optional, if Hit_Writeback_D is implemented, the S and T variants are recommended.
0b111	I, D	Fetch and Lock	Address	<p>If the cache does not contain the specified address, fill it from memory, performing a write-back if required. Set the state to valid and locked.</p> <p>If the cache already contains the specified address, set the state to locked. In set-associative or fully-associative caches, the way selected on a fill from memory is implementation dependent.</p> <p>The lock state may be cleared by executing an Index Invalidate, Index Writeback Invalidate, Hit Invalidate, or Hit Writeback Invalidate operation to the locked line, or via an Index Store Tag operation to the line that clears the lock bit. Clearing the lock state via Index Store Tag is dependent on the implementation-dependent cache tag and cache line organization, and that Index and Index Writeback Invalidate operations are dependent on cache line organization. Only Hit and Hit Writeback Invalidate operations are generally portable across implementations.</p> <p>It is implementation dependent whether a locked line is displaced as the result of an external invalidate or intervention that hits on the locked line. Software must not depend on the locked line remaining in the cache if an external invalidate or intervention would invalidate the line if it were not locked.</p> <p>It is implementation dependent whether a Fetch and Lock operation affects more than one line. For example, more than one line around the referenced address may be fetched and locked. It is recommended that only the single line containing the referenced address be affected.</p>	Recommended

Restrictions:

The operation of this instruction is **UNDEFINED** for any operation/cache combination that is not implemented.

The operation of this instruction is **UNDEFINED** if the operation requires an address, and that address is uncachable.

The operation of the instruction is **UNPREDICTABLE** if the cache line that contains the CACHE instruction is the target of an invalidate or a writeback invalidate.

If this instruction is used to lock all ways of a cache at a specific cache index, the behavior of that cache to subsequent cache misses to that cache index is **UNDEFINED**.

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Any use of this instruction that can cause cacheline writebacks should be followed by a subsequent SYNC instruction to avoid hazards where the writeback data is not yet visible at the next level of the memory hierarchy.

This instruction does not produce an exception for a misaligned memory address, since it has no memory access size.

Availability and Compatibility:

This instruction has been reallocated an opcode in Release 6.

Operation:

```
vAddr ← GPR[base] + sign_extend(offset)
(pAddr, uncached) ← AddressTranslation(vAddr, DataReadReference)
CacheOp(op, vAddr, pAddr)
```

Exceptions:

TLB Refill Exception.

TLB Invalid Exception

Coprocessor Unusable Exception

Address Error Exception

Cache Error Exception

Bus Error Exception

Programming Notes:

As shown in the instruction drawing above, Release 6 architecture implements a 9-bit offset, whereas all release levels lower than Release 6 of the MIPS architecture implement a 16-bit offset.

For cache operations that require an index, it is implementation dependent whether the effective address or the translated physical address is used as the cache index. Therefore, the index value should always be converted to an unmapped address (such as an kseg0 address - by ORing the index with 0x80000000 before being used by the cache instruction). For example, the following code sequence performs a data cache Index Store Tag operation using the index passed in GPR a0:

```
li    a1, 0x80000000    /* Base of kseg0 segment */
or    a0, a0, a1        /* Convert index to kseg0 address */
cache DCIndexStTag, 0(a1) /* Perform the index store tag operation */
```

Format: CACHEE op, offset(base)

MIPS32

Purpose: Perform Cache Operation EVA

To perform the cache operation specified by op using a user mode virtual address while in kernel mode.

Description:

The 9-bit offset is sign-extended and added to the contents of the base register to form an effective address. The effective address is used in one of the following ways based on the operation to be performed and the type of cache as described in the following table.

Table 3.7 Usage of Effective Address

Operation Requires an	Type of Cache	Usage of Effective Address
Address	Virtual	The effective address is used to address the cache. An address translation may or may not be performed on the effective address (with the possibility that a TLB Refill or TLB Invalid exception might occur)
Address	Physical	The effective address is translated by the MMU to a physical address. The physical address is then used to address the cache
Index	N/A	<p>The effective address is translated by the MMU to a physical address. It is implementation dependent whether the effective address or the translated physical address is used to index the cache. As such, a kseg0 address should always be used for cache operations that require an index. See the Programming Notes section below.</p> <p>Assuming that the total cache size in bytes is CS, the associativity is A, and the number of bytes per tag is BPT, the following calculations give the fields of the address which specify the way and the index:</p> $\begin{aligned} \text{OffsetBit} &\leftarrow \text{Log2}(\text{BPT}) \\ \text{IndexBit} &\leftarrow \text{Log2}(\text{CS} / \text{A}) \\ \text{WayBit} &\leftarrow \text{IndexBit} + \text{Ceiling}(\text{Log2}(\text{A})) \\ \text{Way} &\leftarrow \text{Addr}_{\text{WayBit}-1..\text{IndexBit}} \\ \text{Index} &\leftarrow \text{Addr}_{\text{IndexBit}-1..\text{OffsetBit}} \end{aligned}$ <p>For a direct-mapped cache, the Way calculation is ignored and the Index value fully specifies the cache tag. This is shown symbolically in the figure below.</p>

Figure 3.4 Usage of Address Fields to Select Index and Way

A TLB Refill and TLB Invalid (both with cause code equal TLBL) exception can occur on any operation. For index

operations (where the address is used to index the cache but need not match the cache tag) software should use unmapped addresses to avoid TLB exceptions. This instruction never causes TLB Modified exceptions nor TLB Refill exceptions with a cause code of TLBS. This instruction never causes Execute-Inhibit nor Read-Inhibit exceptions.

The effective address may be an arbitrarily-aligned by address. The CACHEE instruction never causes an Address Error Exception due to a non-aligned address.

A Cache Error exception may occur as a by-product of some operations performed by this instruction. For example, if a Writeback operation detects a cache or bus error during the processing of the operation, that error is reported via a Cache Error exception. Similarly, a Bus Error Exception may occur if a bus operation invoked by this instruction is terminated in an error. However, cache error exceptions must not be triggered by an Index Load Tag or Index Store tag operation, as these operations are used for initialization and diagnostic purposes.

An Address Error Exception (with cause code equal AdEL) may occur if the effective address references a portion of the kernel address space which would normally result in such an exception. It is implementation dependent whether such an exception does occur.

It is implementation dependent whether a data watch is triggered by a cache instruction whose address matches the Watch register address match conditions.

The CACHEE instruction and the memory transactions which are sourced by the CACHEE instruction, such as cache refill or cache writeback, obey the ordering and completion rules of the SYNC instruction.

Bits [17:16] of the instruction specify the cache on which to perform the operation, as follows:

Table 3.8 Encoding of Bits[17:16] of CACHEE Instruction

Code	Name	Cache
0b00	I	Primary Instruction
0b01	D	Primary Data or Unified Primary
0b10	T	Tertiary
0b11	S	Secondary

Bits [20:18] of the instruction specify the operation to perform. To provide software with a consistent base of cache operations, certain encodings must be supported on all processors. The remaining encodings are recommended

When implementing ~~For implementations which implement~~ multiple level of caches and where the hardware maintains the smaller cache as a proper subset of a larger cache (~~every address which is resident in the smaller cache is also resident in the larger cache; also known as the inclusion property~~), it is recommended that the CACHEE instructions ~~which operate on the larger, outer level cache;~~ must first operate on the smaller, inner-level cache. For example, a Hit_Writeback_Invalidate operation targeting the Secondary cache, must first operate on the primary data cache first. If the CACHEE instruction implementation does not follow this policy then any software which flushes the caches must mimic this behavior. That is, the software sequences must first operate on the inner cache then operate on the outer cache. The software must place a SYNC instruction after the CACHEE instruction whenever there are possible writebacks from the inner cache to ensure that the writeback data is resident in the outer cache before operating on the outer cache. If neither the CACHEE instruction implementation nor the software cache flush sequence follow this policy, then the inclusion property of the caches can be broken, which might be a condition that the cache management hardware cannot properly deal with.

When implementing multiple level of caches without the inclusion property, you must use SYNC instruction after the CACHEE instruction whenever writeback data has to be resident in the next level of memory hierarchy.

For multiprocessor implementations that maintain coherent caches, some of the Hit type of CACHEE instruction

operations may optionally affect all coherent caches within the implementation. If the effective address uses a coherent Cache Coherency Attribute (CCA), then the operation is *globalized*, meaning it is broadcast to all of the coherent caches within the system. If the effective address does not use one of the coherent CCAs, there is no broadcast of the operation. If multiple levels of caches are to be affected by one CACHEE instruction, all of the affected cache levels must be processed in the same manner — either all affected cache levels use the globalized behavior or all affected cache levels use the non-globalized behavior.

The CACHEE instruction functions the same as the CACHE instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to 1.

Table 3.9 Encoding of Bits [20:18] of the CACHEE Instruction

Code	Caches	Name	Effective Address Operand Type	Operation	Compliance Implemented
0b000	I	Index Invalidate	Index	Set the state of the cache block at the specified index to invalid. This required encoding may be used by software to invalidate the entire instruction cache by stepping through all valid indices.	Required
	D	Index Writeback Invalidate / Index Invalidate	Index	For a write-back cache: If the state of the cache block at the specified index is valid and dirty, write the block back to the memory address specified by the cache tag. After that operation is completed, set the state of the cache block to invalid. If the block is valid but not dirty, set the state of the block to invalid.	Required
	S, T	Index Writeback Invalidate / Index Invalidate	Index	For a write-through cache: Set the state of the cache block at the specified index to invalid. This required encoding may be used by software to invalidate the entire data cache by stepping through all valid indices. Note that Index Store Tag should be used to initialize the cache at power up.	Required if S, T cache is implemented
0b001	All	Index Load Tag	Index	Read the tag for the cache block at the specified index into the <i>TagLo</i> and <i>TagHi</i> Coprocessor 0 registers. If the <i>DataLo</i> and <i>DataHi</i> registers are implemented, also read the data corresponding to the byte index into the <i>DataLo</i> and <i>DataHi</i> registers. This operation must not cause a Cache Error Exception. The granularity and alignment of the data read into the <i>DataLo</i> and <i>DataHi</i> registers is implementation-dependent, but is typically the result of an aligned access to the cache, ignoring the appropriate low-order bits of the byte index.	Recommended

Table 3.9 Encoding of Bits [20:18] of the CACHEE Instruction (Continued)

Code	Caches	Name	Effective Address Operand Type	Operation	Compliance Implemented
0b010	All	Index Store Tag	Index	Write the tag for the cache block at the specified index from the <i>TagLo</i> and <i>TagHi</i> Coprocessor 0 registers. This operation must not cause a Cache Error Exception. This required encoding may be used by software to initialize the entire instruction or data caches by stepping through all valid indices. Doing so requires that the <i>TagLo</i> and <i>TagHi</i> registers associated with the cache be initialized first.	Required
0b011	All	Implementation Dependent	Unspecified	Available for implementation-dependent operation.	Optional
0b100	I, D	Hit Invalidate	Address	If the cache block contains the specified address, set the state of the cache block to invalid. This required encoding may be used by software to invalidate a range of addresses from the instruction cache by stepping through the address range by the line size of the cache.	Required (Instruction Cache Encoding Only), Recommended otherwise
	S, T	Hit Invalidate	Address	In multiprocessor implementations with coherent caches, the operation may optionally be broadcast to all coherent caches within the system.	Optional, if Hit_Invalidate_D is implemented, the S and T variants are recommended.
0b101	I	Fill	Address	Fill the cache from the specified address.	Recommended
	D	Hit Writeback Invalidate / Hit Invalidate	Address	For a write-back cache: If the cache block contains the specified address and it is valid and dirty, write the contents back to memory. After that operation is completed, set the state of the cache block to invalid. If the block is valid but not dirty, set the state of the block to invalid.	Required
	S, T	Hit Writeback Invalidate / Hit Invalidate	Address	For a write-through cache: If the cache block contains the specified address, set the state of the cache block to invalid. This required encoding may be used by software to invalidate a range of addresses from the data cache by stepping through the address range by the line size of the cache. In multiprocessor implementations with coherent caches, the operation may optionally be broadcast to all coherent caches within the system.	Required if S, T cache is implemented

Table 3.9 Encoding of Bits [20:18] of the CACHEE Instruction (Continued)

Code	Caches	Name	Effective Address Operand Type	Operation	Compliance Implemented
0b110	D	Hit Writeback	Address	<p>If the cache block contains the specified address and it is valid and dirty, write the contents back to memory. After the operation is completed, leave the state of the line valid, but clear the dirty state. For a write-through cache, this operation may be treated as a nop.</p> <p>In multiprocessor implementations with coherent caches, the operation may optionally be broadcast to all coherent caches within the system.</p>	Recommended
	S, T	Hit Writeback	Address		Optional, if Hit_Writeback_D is implemented, the S and T variants are recommended.
0b111	I, D	Fetch and Lock	Address	<p>If the cache does not contain the specified address, fill it from memory, performing a write-back if required. Set the state to valid and locked.</p> <p>If the cache already contains the specified address, set the state to locked. In set-associative or fully-associative caches, the way selected on a fill from memory is implementation dependent.</p> <p>The lock state may be cleared by executing an Index Invalidate, Index Writeback Invalidate, Hit Invalidate, or Hit Writeback Invalidate operation to the locked line, or via an Index Store Tag operation to the line that clears the lock bit. Clearing the lock state via Index Store Tag is dependent on the implementation-dependent cache tag and cache line organization, and that Index and Index Writeback Invalidate operations are dependent on cache line organization. Only Hit and Hit Writeback Invalidate operations are generally portable across implementations.</p> <p>It is implementation dependent whether a locked line is displaced as the result of an external invalidate or intervention that hits on the locked line. Software must not depend on the locked line remaining in the cache if an external invalidate or intervention would invalidate the line if it were not locked.</p> <p>It is implementation dependent whether a Fetch and Lock operation affects more than one line. For example, more than one line around the referenced address may be fetched and locked. It is recommended that only the single line containing the referenced address be affected.</p>	Recommended

Restrictions:

The operation of this instruction is **UNDEFINED** for any operation/cache combination that is not implemented.

The operation of this instruction is **UNDEFINED** if the operation requires an address, and that address is uncacheable.

The operation of the instruction is **UNPREDICTABLE** if the cache line that contains the CACHEE instruction is the target of an invalidate or a writeback invalidate.

If this instruction is used to lock all ways of a cache at a specific cache index, the behavior of that cache to subsequent cache misses to that cache index is **UNDEFINED**.

Any use of this instruction that can cause cacheline writebacks should be followed by a subsequent SYNC instruction to avoid hazards where the writeback data is not yet visible at the next level of the memory hierarchy.

Only usable when access to Coprocessor0 is enabled and when accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

This instruction does not produce an exception for a misaligned memory address, since it has no memory access size.

Operation:

```
vAddr ← GPR[base] + sign_extend(offset)
(pAddr, uncached) ← AddressTranslation(vAddr, DataReadReference)
CacheOp(op, vAddr, pAddr)
```

Exceptions:

TLB Refill Exception.

TLB Invalid Exception

Coprocessor Unusable Exception

Reserved Instruction

Address Error Exception

Cache Error Exception

Bus Error Exception

Programming Notes:

For cache operations that require an index, it is implementation dependent whether the effective address or the translated physical address is used as the cache index. Therefore, the index value should always be converted to a kseg0 address by ORing the index with 0x80000000 before being used by the cache instruction. For example, the following code sequence performs a data cache Index Store Tag operation using the index passed in GPR a0:

```
li    a1, 0x80000000    /* Base of kseg0 segment */
or     a0, a0, a1        /* Convert index to kseg0 address */
cache DCIndexStTag, 0(a1) /* Perform the index store tag operation */
```

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt					0 00000	fs		fd		CEIL.L 001010
6	5					5	5		5		6

Format: CEIL.L.fmt
 CEIL.L.S fd, fs
 CEIL.L.D fd, fs

MIPS32 Release 2
 MIPS32 Release 2

Purpose: Fixed Point Ceiling Convert to Long Fixed Point

To convert an FP value to 64-bit fixed point, rounding up.

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

The value in FPR *fs*, in format *fmt*, is converted to a value in 64-bit long fixed point format and rounding toward $+\infty$ (rounding mode 2). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{63} to $2^{63}-1$, the result cannot be represented correctly, an IEEE Invalid Operation condition exists, and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, $2^{63}-1$, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs: *fs* for type *fmt* and *fd* for long fixed point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Operation:

$\text{StoreFPR}(fd, L, \text{ConvertFmt}(\text{ValueFPR}(fs, \text{fmt}), \text{fmt}, L))$

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt					0 00000	fs		fd		CEIL.W 001110

Format: CEIL.W.fmt

CEIL.W.S fd, fs

CEIL.W.D fd, fs

MIPS32

MIPS32

Purpose: Floating Point Ceiling Convert to Word Fixed Point

To convert an FP value to 32-bit fixed point, rounding up

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

The value in $FPR.fs$, in format fmt , is converted to a value in 32-bit word fixed point format and rounding toward $+\infty$ (rounding mode 2). The result is placed in $FPR.fd$.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{31} to $2^{31}-1$, the result cannot be represented correctly, an IEEE Invalid Operation condition exists, and the Invalid Operation flag is set in the $FCSR$. If the Invalid Operation *Enable* bit is set in the $FCSR$, no result is written to fd and an Invalid Operation exception is taken immediately. Otherwise, the default result, $2^{31}-1$, is written to fd .

Restrictions:

The fields fs and fd must specify valid FPRs; fs for type fmt and fd for word fixed point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format fmt ; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

$\text{StoreFPR}(fd, W, \text{ConvertFmt}(\text{ValueFPR}(fs, fmt), fmt, W))$

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact

Format: CFC1 rt, fs

MIPS32

Purpose: Move Control Word From Floating Point

To copy a word from an FPU control register to a GPR.

Description: $GPR[rt] \leftarrow FP_Control[fs]$

Copy the 32-bit word from FP (coprocessor 1) control register *fs* into GPR *rt*.

UFR (User FR change facility):

The definition of this instruction has been extended in Release 5 to support user mode read of *Status_{FR}* under the control of *Config5_{UFR}*. This required feature is meant to facilitate transition from *FR*=0 to *FR*=1 floating-point register modes in order to obsolete *FR*=0 mode.

The UFR facility is removed in Release 6. Accessing the UFR and UNFR registers either cannot occur because Release 6 does not allow *FIR_{UFRP}* to be set, or is required to produce a Reserved Instruction Exception.

Restrictions:

There are a few control registers defined for the floating point unit. The result is **UNPREDICTABLE** if *fs* specifies a register that does not exist.

The result is **UNPREDICTABLE** if *fs* specifies the UNFR write-only control. R5.03 implementations are required to produce a Reserved Instruction Exception; software must assume it is **UNPREDICTABLE**.

Operation:

```

if fs = 0 then
    temp ← FIR
elseif fs = 1 then /* read UFR (CPl Register 1) */
    if FIRUFRP then
        if not Config5UFR then signalException(RI) endif
        temp ← StatusFR
    else
        if Config2.AR>=2 SignalException(RI) /* MIPS Release 6 traps */ endif
        temp ← UNPREDICTABLE
    endif
elseif fs = 4 then /* read fs=4 UNFR not supported for reading - UFR suffices */
    if Config2.AR>=2 SignalException(RI) /* MIPS Release 6 traps */ endif
    temp ← UNPREDICTABLE
elseif fs = 25 then /* FCCR */
    temp ← 024 || FCSR31..25 || FCSR23
elseif fs = 26 then /* FEXR */
    temp ← 014 || FCSR17..12 || 05 || FCSR6..2 || 02
elseif fs = 28 then /* FENR */
    temp ← 020 || FCSR11..7 || 04 || FCSR24 || FCSR1..0
elseif fs = 31 then /* FCSR */
    temp ← FCSR
else

```

```
    temp ← UNPREDICTABLE
endif

GPR[rt] ← temp
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Historical Information:

For the MIPS I, II and III architectures, the contents of GPR *rt* are **UNPREDICTABLE** for the instruction immediately following CFC1.

MIPS V and MIPS32 introduced the three control registers that access portions of FCSR. These registers were not available in MIPS I, II, III, or IV.

MIPS32 Release 5 introduced the UFR and UNFR register aliases that allow user level access to *Status_{FR}*. Release 6 removes them.

Format: CFC2 rt, Impl

MIPS32

The syntax shown above is an example using CFC1 as a model. The specific syntax is implementation dependent.

Purpose: Move Control Word From Coprocessor 2

To copy a word from a Coprocessor 2 control register to a GPR

Description: $GPR[rt] \leftarrow CP2CCR[Impl]$

Copy the 32-bit word from the Coprocessor 2 control register denoted by the *Impl* field. The interpretation of the *Impl* field is left entirely to the Coprocessor 2 implementation and is not specified by the architecture.

Restrictions:

The result is **UNPREDICTABLE** if *Impl* specifies a register that does not exist.

Operation:

```
temp ← CP2CCR[Impl]
GPR[rt] ← temp
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Format: CLASS.fmt

CLASS.S fd, fs

CLASS.D fd, fs

MIPS32 Release 6

MIPS32 Release 6

Purpose: Scalar Floating-Point Class Mask

Scalar floating-point class shown as a bit mask for Zero, Negative, Infinite, Subnormal, Quiet NaN, or Signaling NaN.

Description: $FPR[fd] \leftarrow class(FPR[fs])$

Stores in *fd* a bit mask reflecting the floating-point class of the floating point scalar value *fs*.

The mask has 10 bits as follows. Bits 0 and 1 indicate NaN values: signaling NaN (bit 0) and quiet NaN (bit 1). Bits 2, 3, 4, 5 classify negative values: infinity (bit 2), normal (bit 3), subnormal (bit 4), and zero (bit 5). Bits 6, 7, 8, 9 classify positive values: infinity (bit 6), normal (bit 7), subnormal (bit 8), and zero (bit 9).

This instruction corresponds to the **class** operation of the IEEE Standard for Floating-Point Arithmetic 754™-2008. This scalar FPU instruction also corresponds to the vector FCLASS.df instruction of MSA.

The input values and generated bit masks are not affected by the flush-subnormal-to-zero mode FCSR.FS.

The input operand is a scalar value in floating-point data format *fmt*. Bits beyond the width of *fmt* are ignored. The result is a 10-bit bitmask as described above, zero extended to 32-bits. Coprocessor register bits beyond 32-bits are UNPREDICTABLE (e.g. bits 32-63 are UNPREDICTABLE on a 64-bit FPU, while bits 32-128 bits are UNPREDICTABLE if the processor supports MSA).

Restrictions:

No data-dependent exceptions are possible.

Availability and Compatibility:

This instruction is introduced by and required as of Release 6.

CLASS.fmt is defined only for formats S and D. Other formats must produce a Reserved Instruction Exception (unless used for a different instruction).

Operation:

```

CLASS.fmt
if not IsCoprorocessorEnabled(1)
    then SignalException(CoprocessorUnusable, 1) end if
if not IsFloatingPointImplemented(fmt)
    then SignalException(ReservedInstruction) end if
if fmt=D and FIR.D=0
    then SignalFPEException(UnimplementedOperation) end if

fin ← ValueFPR(fs,fmt)
masktmp ← ClassFP(fin, fmt)
StoreFPR (fd, fmt, ftmp)
/* end of instruction */

```

```
function ClassFP(tt, ts, n)
/* Implementation defined class operation. */
endfunction ClassFP
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation

pre-Release 6

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL2 011100	rs	rt	rd	0 00000	CLO 100001						
6	5	5	5	5	6						

Release 6

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL 000000	rs	00000	rd	00001	CLO 010001						
6	5	5	5	5	6						

Format: CLO rd, rs**MIPS32****Purpose:** Count Leading Ones in Word

To count the number of leading ones in a word.

Description: $GPR[rd] \leftarrow \text{count_leading_ones } GPR[rs]$

Bits 31..0 of GPR *rs* are scanned from most significant to least significant bit. The number of leading ones is counted and the result is written to GPR *rd*. If all of bits **31..0** were set in GPR *rs*, the result written to GPR *rd* is 32.

Restrictions:

To be compliant with the MIPS32 Architecture, software must place the same GPR number in both the *rt* and *rd* fields of the instruction. The operation of the instruction is **UNPREDICTABLE** if the *rt* and *rd* fields of the instruction contain different values.

Availability and Compatibility:

This instruction has been reallocated an opcode in Release 6.

Operation:

```

temp ← 32
for i in 31 .. 0
    if GPR[rs]i = 0 then
        temp ← 31 - i
        break
    endif
endfor
GPR[rd] ← temp

```

Exceptions:

None

Programming Notes:

As shown in the instruction drawing above, the Release 6 architecture sets the 'rt' field to a value of 00000.

pre-Release 6

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL2 011100	rs	rt	rd	0 00000	CLZ 100000						
6	5	5	5	5	6						

Release 6

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL 000000	rs	00000	rd	00001	CLZ 010000						
6	5	5	5	5	6						

Format: CLZ rd, rs**MIPS32****Purpose:** Count Leading Zeros in Word

Count the number of leading zeros in a word.

Description: $\text{GPR}[\text{rd}] \leftarrow \text{count_leading_zeros } \text{GPR}[\text{rs}]$

Bits **31..0** of GPR *rs* are scanned from most significant to least significant bit. The number of leading zeros is counted and the result is written to GPR *rd*. If no bits were set in GPR *rs*, the result written to GPR *rd* is 32.

Restrictions:

Pre-Release 6: To be compliant with the MIPS32Architecture, software must place the same GPR number in both the *rt* and *rd* fields of the instruction. The operation of the instruction is **UNPREDICTABLE** if the *rt* and *rd* fields of the instruction contain different values. Release 6's new instruction encoding does not contain an *rt* field.

Availability and Compatibility:

This instruction has been reallocated an opcode in Release 6.

Operation:

```

temp ← 32
for i in 31 .. 0
    if GPR[rs]i = 1 then
        temp ← 31 - i
        break
    endif
endfor
GPR[rd] ← temp

```

Exceptions:

None

Programming Notes:

As shown in the instruction drawing above, Release 6 sets the 'rt' field to a value of 00000.

Format: CMP.condn.fmt

CMP.condn.S fd, fs, ft (with fmt=10100 (W))

CMP.condn.D fd, fs, ft (with fmt=10101 (L))

MIPS32 Release 6

MIPS32 Release 6

Purpose: Floating Point Compare setting Mask.

To compare FP values and record the result as a format-width mask of all 0s or all 1s in a floating point register

Description: $FPR[fd] \leftarrow FPR[fs] \text{ compare_cond } FPR[ft]$

The value in FPR *fs* is compared to the value in FPR *ft*.

The comparison is exact and neither overflows nor underflows.

If the comparison specified by the *condn* field of the instruction is true for the operand values, the result is true; otherwise, the result is false. If no exception is taken, the result is written into FPR *fd*; true is all 1s and false is all 0s, repeated the operand width of *fmt*. All other bits beyond the operand width *fmt* are UNPREDICTABLE. E.g. a 32-bit single precision comparison writes a mask of 32 0s or 1s into bits 0 to 31 of FPR *fd*, and makes bits 32 to 63 to UNPREDICTABLE, if a 64-bit FPU without MSA, or bits 32 to 127 if MSA is present.

The values are in format *fmt*. However, these instructions use a non-standard encoding of *fmt*: *fmt* encoding=10100, which is W (32-bit integer) elsewhere, means S (32-bit single precision floating point) here; *fmt* encoding=10101, which is L (64-bit integer) elsewhere, means D (64-bit double precision floating point) here.

All other encodings, that is all other values of *fmt*, are reserved in Release 6, and produce a Reserved Instruction Exception. The encodings corresponding to MIPS32 Release 5 C.cond.S and C.cond.D are so reserved.

The *condn* field of the instruction specifies the nature of the comparison: equals, less than, and so on, unordered or ordered, signalling or quiet, as specified in [Table 3.10 “Comparing CMP.condn.fmt, IEEE 754-2008, C.cond.fmt, and MSA FP compares” on page 147](#).

Release 6: The *condn* field bits have specific purposes: *cond₄* and *cond_{2..1}* specify the nature of the comparison (equals, less than, and so on); *cond₀* specifies whether the comparison is ordered or unordered, that is false or true if any operand is a NaN; *cond₃* indicates whether the instruction should signal an exception on QNaN inputs. However, in the future the MIPS ISA may be extended in ways that do not preserve these meanings.

All encodings of the *condn* field that are not specified. For example, items shaded in [Table 3.10](#), are reserved in Release 6 and produce a Reserved Instruction exception.

If one of the values is an SNaN, or if a signalling comparison is specified (currently, *cond₃* is set) and at least one of the values is a QNaN, an Invalid Operation condition is raised and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written and an Invalid Operation exception is taken immediately. Otherwise, the mask result is written into FPR *fd*.

There are four mutually exclusive ordering relations for comparing floating point values; one relation is always true and the others are false. The familiar relations are *greater than*, *less than*, and *equal*. In addition, the IEEE floating point standard defines the relation *unordered*, which is true when at least one operand value is NaN; NaN compares unordered with everything, including itself. Comparisons ignore the sign of zero, so +0 equals -0.

The comparison condition is a logical predicate, or equation, of the ordering relations such as *less than or equal*,

equal, *not less than*, or *unordered or equal*. Compare distinguishes among the 16 comparison predicates. The Boolean result of the instruction is obtained by substituting the Boolean value of each ordering relation for the two FP values in the equation. For example: If the *equal* relation is true, then all four example predicates above yield a true result. If the *unordered* relation is true then only the final predicate, *unordered or equal*, yields a true result.

The predicates implemented are described in [Table 3.10 “Comparing CMP.condn.fmt, IEEE 754-2008, C.cond.fmt, and MSA FP compares” on page 147](#). Not all of the 16 IEEE predicates are implemented directly by hardware. For the directed comparisons (LT, LE, GT, GE) the missing predicates can be obtained by reversing the FPR register operands *ft* and *fs*. For example, the hardware implements the “Ordered Less Than” predicate LT(*fs*,*ft*); reversing the operands LT(*ft*,*fs*) produces the dual predicate “Unordered or Greater Than or Equal” UGE(*fs*,*ft*). [Table 3.10](#) shows these mappings. Reversing inputs is ineffective for the symmetric predicates such as EQ; Release 6 implements these negative predicates directly, so that all mask values can be generated in a single instruction.

In addition to showing the comparison predicates, instruction encodings, instruction mnemonics and longer instruction names for CMP.condn.fmt, [Table 3.10](#) provides comparisons to (1) the MIPS32 Release 5 C.cond.fmt, and (2) the (MSA) MIPS SIMD Architecture packed vector floating point comparison instructions. CMP.condn.fmt provides exactly the same comparisons for FPU scalar values that MSA provides for packed vectors, with similar mnemonics. CMP.condn.fmt provides a superset of the MIPS32 Release 5 C.cond.fmt comparisons.

The official Release 6 mnemonics for comparisons have slightly changed. For example, SULT, Signalling Unordered or Less Than. [Table 3.10](#) indicates mnemonics that implement the same predicates.

In addition, [Table 3.10](#) shows the corresponding IEEE 754-2008 comparison operations.

Unimplemented Operation, Invalid Operation

31	26	25	24	0
COP2 010010				CO 1
				cofun
6				1
				25

Format: COP2 func

MIPS32

Purpose: Coprocessor Operation to Coprocessor 2

To perform an operation to Coprocessor 2.

Description: CoprocessorOperation(2, cofun)

An implementation-dependent operation is performed to Coprocessor 2, with the *cofun* value passed as an argument. The operation may specify and reference internal coprocessor registers, and may change the state of the coprocessor conditions, but does not modify state within the processor. Details of coprocessor operation and internal state are described in the documentation for each Coprocessor 2 implementation.

Restrictions:

Operation:

CoprocessorOperation(2, cofun)

Exceptions:

Coprocessor Unusable

Reserved Instruction

Format: CTC1 rt, fs

MIPS32

Purpose: Move Control Word to Floating Point

To copy a word from a GPR to an FPU control register.

Description: $FP_Control[fs] \leftarrow GPR[rt]$

Copy the low word from GPR *rt* into the FP (coprocessor 1) control register indicated by *fs*.

Writing to the floating point *Control/Status* register, the *FCSR*, causes the appropriate exception if any *Cause* bit and its corresponding *Enable* bit are both set. The register is written before the exception occurs. Writing to *FEXR* to set a cause bit whose enable bit is already set, or writing to *FENR* to set an enable bit whose cause bit is already set causes the appropriate exception. The register is written before the exception occurs and the *EPC* register contains the address of the CTC1 instruction.

UFR (User FR change facility):

The definition of this instruction has been extended in Release 5 to support user mode read of *Status_{FR}* under the control of *Config5_{UFR}*. This required feature is meant to facilitate transition from *FR*=0 to *FR*=1 floating-point register modes in order to obsolete *FR*=0 mode.

The UFR facility is removed in Release 6. Accessing the UFR and UNFR registers either cannot occur because Release 6 does not allow *FIR_{UFRP}* to be set, or is required to produce a Reserved Instruction Exception.

Restrictions:

There are a few control registers defined for the floating point unit. The result is **UNPREDICTABLE** if *fs* specifies a register that does not exist.

Furthermore, the result is **UNPREDICTABLE** if *fd* specifies the UFR or UNFR aliases, with *fs* anything other than 00000, GPR[0]. R5.03 implementations are required to produce a Reserved Instruction Exception; software must assume it is **UNPREDICTABLE**.

Operation:

```
temp ← GPR[rt]31..0
if (fs = 1 or fs = 4) then
    /* clear UFR or UNFR(CP1 Register 1) */
    if Config2.AR ≥ 2 SignalException(RI) /* MIPS Release 6 traps */ endif
    if not (rt = 0 and FIRUFRP) then UNPREDICTABLE /*end of instruction*/ endif
    if not Config5UFR then signalException(RI) endif?
    if fs = 1 then StatusFR ← 0
    elseif fs = 4 then StatusFR ← 1
    else /* cannot happen */
elseif fs = 25 then /* FCCR */
    if temp31..8 ≠ 024 then
        UNPREDICTABLE
    else
        FCSR ← temp7..1 || FCSR24 || temp0 || FCSR22..0
```

```

    endif
elseif fs = 26 then /* FEXR */
    if temp31..18 ≠ 0 or temp11..7 ≠ 0 or temp2..0 ≠ 0 then
        UNPREDICTABLE
    else
        FCSR ← FCSR31..18 || temp17..12 || FCSR11..7 ||
            temp6..2 || FCSR1..0
    endif
elseif fs = 28 then /* FENR */
    if temp31..12 ≠ 0 or temp6..3 ≠ 0 then
        UNPREDICTABLE
    else
        FCSR ← FCSR31..25 || temp2 || FCSR23..12 || temp11..7
            || FCSR6..2 || temp1..0
    endif
elseif fs = 31 then /* FCSR */
    if (FCSRImpl field is not implemented) and (temp22..18 ≠ 0) then

    elseif (FCSRImpl field is implemented) and temp20..18 ≠ 0 then
        UNPREDICTABLE
    else
        FCSR ← temp
    endif
else
    UNPREDICTABLE
endif

CheckFPException()

```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation, Invalid Operation, Division-by-zero, Inexact, Overflow, Underflow

Historical Information:

For the MIPS I, II and III architectures, the contents of floating point control register *fs* are **UNPREDICTABLE** for the instruction immediately following CTC1.

MIPS V and MIPS32 introduced the three control registers that access portions of *FCSR*. These registers were not available in MIPS I, II, III, or IV.

MIPS32 Release 5 introduced the UFR and UNFR register aliases that allow user level access to *Status_{FR}*.

Format: CTC2 rt, Impl

MIPS32

The syntax shown above is an example using CTC1 as a model. The specific syntax is implementation dependent.

Purpose: Move Control Word to Coprocessor 2

To copy a word from a GPR to a Coprocessor 2 control register.

Description: $CP2CCR[Impl] \leftarrow GPR[rt]$

Copy the low word from GPR *rt* into the Coprocessor 2 control register denoted by the *Impl* field. The interpretation of the *Impl* field is left entirely to the Coprocessor 2 implementation and is not specified by the architecture.

Restrictions:

The result is **UNPREDICTABLE** if *rd* specifies a register that does not exist.

Operation:

```
temp ← GPR[rt]
CP2CCR[Impl] ← temp
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Format: CVT.D.fmt
 CVT.D.S fd, fs
 CVT.D.W fd, fs
 CVT.D.L fd, fs

MIPS32
MIPS32
MIPS32 Release 2

Purpose: Floating Point Convert to Double Floating Point

To convert an FP or fixed point value to double FP.

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

The value in FPR *fs*, in format *fmt*, is converted to a value in double floating point format and rounded according to the current rounding mode in *FCSR*. The result is placed in FPR *fd*. If *fmt* is S or W, then the operation is always exact.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs, *fs* for type *fmt* and *fd* for double floating point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

For CVT.D.L, the result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model; i.e. it is the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Operation:

$\text{StoreFPR}(fd, D, \text{ConvertFmt}(\text{ValueFPR}(fs, fmt), fmt, D))$

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact

 CVT.L.S fd, fs
 CVT.L.D fd, fs

MIPS32 Release 2
MIPS32 Release 2

Purpose: Floating Point Convert to Long Fixed Point

To convert an FP value to a 64-bit fixed point.

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

Convert the value in format *fmt* in FPR *fs* to long fixed point format and round according to the current rounding mode in *FCSR*. The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{63} to $2^{63}-1$, the result cannot be represented correctly, an IEEE Invalid Operation condition exists, and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, $2^{63}-1$, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs, *fs* for type *fmt* and *fd* for long fixed point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Operation:

$\text{StoreFPR}(fd, L, \text{ConvertFmt}(\text{ValueFPR}(fs, fmt), fmt, L))$

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact,

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt 10000		ft		fs		fd		CVT.PS 100110		
6	5		5		5		5		6		

Format: CVT.PS.S *fd*, *fs*, *ft*

MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Convert Pair to Paired Single

To convert two FP values to a paired single value.

Description: $\text{FPR}[\text{fd}] \leftarrow \text{FPR}[\text{fs}]_{31..0} \parallel \text{FPR}[\text{ft}]_{31..0}$

The single-precision values in FPR *fs* and *ft* are written into FPR *fd* as a paired-single value. The value in FPR *fs* is written into the upper half, and the value in FPR *ft* is written into the lower half.

CVT.PS.S is similar to PLL.PS, except that it expects operands of format *S* instead of *PS*.

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs* and *ft* must specify FPRs valid for operands of type *S*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *S*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

`StoreFPR(fd, S, ValueFPR(fs,S) || ValueFPR(ft,S))`

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation

31	26	25	21	20	16	15	11	10	6	5	0

6	5		5		5		5		6		

Format: CVT.S.PL fd, fs

MIPS32 Release 2, removed in Release 6

Purpose:

Floating Point Convert Pair Lower to Single Floating Point

To convert one half of a paired single FP value to single FP.

Description: $FPR[fd] \leftarrow FPR[fs]_{31..0}$

The lower paired single value in FPR *fs*, in format *PS*, is converted to a value in single floating point format. The result is placed in FPR *fd*. This instruction can be used to isolate the lower half of a paired single value.

The operation is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs—*fs* for type *PS* and *fd* for single floating point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *PS*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of CVT.S.PL is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

StoreFPR (fd, S, ConvertFmt(ValueFPR(fs, PS), PL, S))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

6			5		5		5		5		6

Format: CVT.S.PU *fd*, *fs*

MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Convert Pair Upper to Single Floating Point

To convert one half of a paired single FP value to single FP

Description: $FPR[fd] \leftarrow FPR[fs]_{63..32}$

The upper paired single value in FPR *fs*, in format *PS*, is converted to a value in single floating point format. The result is placed in FPR *fd*. This instruction can be used to isolate the upper half of a paired single value.

The operation is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs—*fs* for type *PS* and *fd* for single floating point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *PS*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of CVT.S.PU is **UNPREDICTABLE** if the processor is executing the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU

Availability and Compatibility:

This instruction was removed in Release 6.

Operation:

StoreFPR (*fd*, *S*, ConvertFmt(ValueFPR(*fs*, *PS*), PU, *S*))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt		0 00000		fs		fd		CVT.S 100000		
6	5		5		5		5		6		

Format: CVT.S.fmt
 CVT.S.D fd, fs
 CVT.S.W fd, fs
 CVT.S.L fd, fs

MIPS32
MIPS32
MIPS32 Release 2

Purpose: Floating Point Convert to Single Floating Point

To convert an FP or fixed point value to single FP.

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

The value in FPR *fs*, in format *fmt*, is converted to a value in single floating point format and rounded according to the current rounding mode in *FCSR*. The result is placed in FPR *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs—*fs* for type *fmt* and *fd* for single floating point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

For CVT.S.L, the result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Operation:

$\text{StoreFPR}(fd, S, \text{ConvertFmt}(\text{ValueFPR}(fs, fmt), fmt, S))$

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact, Overflow, Underflow

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt					0 00000	fs		fd		CVT.W 100100
6	5					5	5		5		6

Format: CVT.W.fmt
 CVT.W.S fd, fs
 CVT.W.D fd, fs

MIPS32
MIPS32

Purpose: Floating Point Convert to Word Fixed Point

To convert an FP value to 32-bit fixed point.

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

The value in FPR *fs*, in format *fmt*, is converted to a value in 32-bit word fixed point format and rounded according to the current rounding mode in *FCSR*. The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{31} to $2^{31}-1$, the result cannot be represented correctly, an IEEE Invalid Operation condition exists, and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, $2^{31}-1$, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs: *fs* for type *fmt* and *fd* for word fixed point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

`StoreFPR(fd, W, ConvertFmt(ValueFPR(fs, fmt), fmt, W))`

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact

Format: DDIV rs, rt

MIPS64, removed in Release 6

Purpose: Doubleword Divide

To divide 64-bit signed integers.

Description: (LO, HI) ← GPR[rs] / GPR[rt]

The 64-bit doubleword in GPR *rs* is divided by the 64-bit doubleword in GPR *rt*, treating both operands as signed values. The 64-bit quotient is placed into special register *LO* and the 64-bit remainder is placed into special register *HI*.

No arithmetic exception occurs under any circumstances.

Restrictions:

If the divisor in GPR *rt* is zero, the arithmetic result value is **UNPREDICTABLE**.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

LO ← GPR[rs] div GPR[rt]
HI ← GPR[rs] mod GPR[rt]

Exceptions:

Reserved Instruction

Programming Notes:

See “Programming Notes” for the DIV instruction.

Historical Perspective:

In MIPS III, if either of the two instructions preceding the divide is an MFHI or MFLO, the result of the MFHI or MFLO is **UNPREDICTABLE**. Reads of the *HI* or *LO* special register must be separated from subsequent instructions that write to them by two or more instructions. This restriction was removed in MIPS IV and MIPS32 and all subsequent levels of the architecture.

Format: DDIVU rs, rt

MIPS64, removed in Release 6

Purpose: Doubleword Divide Unsigned

To divide 64-bit unsigned integers.

Description: $(LO, HI) \leftarrow GPR[rs] / GPR[rt]$

The 64-bit doubleword in GPR *rs* is divided by the 64-bit doubleword in GPR *rt*, treating both operands as unsigned values. The 64-bit quotient is placed into special register *LO* and the 64-bit remainder is placed into special register *HI*.

No arithmetic exception occurs under any circumstances.

Restrictions:

If the divisor in GPR *rt* is zero, the arithmetic result value is **UNPREDICTABLE**.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

$$\begin{aligned} q &\leftarrow (0 \parallel GPR[rs]) \text{ div } (0 \parallel GPR[rt]) \\ r &\leftarrow (0 \parallel GPR[rs]) \text{ mod } (0 \parallel GPR[rt]) \\ LO &\leftarrow q_{63..0} \\ HI &\leftarrow r_{63..0} \end{aligned}$$

Exceptions:

Reserved Instruction

Programming Notes:

See “Programming Notes” for the DIV instruction.

Historical Perspective:

In MIPS III, if either of the two instructions preceding the divide is an MFHI or MFLO, the result of the MFHI or MFLO is **UNPREDICTABLE**. Reads of the *HI* or *LO* special register must be separated from subsequent instructions that write to them by two or more instructions. This restriction was removed in MIPS IV and MIPS32 and all subsequent levels of the architecture.

31	26	25	24		6	5	0
COP0 010000	CO 1	0 000 0000 0000 0000 0000				DERET 011111	
6	1	19				6	

Format: DERET**EJTAG****Purpose:** Debug Exception Return

To Return from a debug exception.

Description:

DERET clears execution and instruction hazards, returns from Debug Mode and resumes non-debug execution at the instruction whose address is contained in the *DEPC* register. DERET does not execute the next instruction (i.e. it has no delay slot).

Restrictions:

A DERET placed between an LL and SC instruction does not cause the SC to fail.

If the *DEPC* register with the return address for the DERET was modified by an MTC0 or a DMTC0 instruction, a CP0 hazard exists that must be removed via software insertion of the appropriate number of SSNOP instructions (for implementations of Release 1 of the Architecture) or by an EHB, or other execution hazard clearing instruction (for implementations of Release 2 of the Architecture).

DERET implements a software barrier that resolves all execution and instruction hazards created by Coprocessor 0 state changes (for Release 2 implementations, refer to the SYNCI instruction for additional information on resolving instruction hazards created by writing the instruction stream). The effects of this barrier are seen starting with the instruction fetch and decode of the instruction at the PC to which the DERET returns.

This instruction is legal only if the processor is executing in Debug Mode.

Pre-Release 6: The operation of the processor is **UNDEFINED** if a DERET is executed in the delay slot of a branch or jump instruction.

Release 6 implementations are required to signal a Reserved Instruction Exception if DERET is encountered in the delay slot or forbidden slot of a branch or jump instruction.

Operation:

```

DebugDM ← 0
DebugIEXI ← 0
if IsMIPS16Implemented() | (Config3ISA > 0) then
    PC ← DEPC31..1 || 0
    ISAMode ← DEPC0
else
    PC ← DEPC
endif
ClearHazards()

```

Exceptions:

Coprocessor Unusable Exception
Reserved Instruction Exception

31	26	25	21	20	16	15	11	10	6	5	4	3	2	0
COP0 0100 00		MFMC0 01 011		rt		12 0110 0		0 000 00		sc 0	0 0 0		0 000	
6		5		5		5		5		1	2		3	

Format: DI
DI rt

MIPS32 Release 2
MIPS32 Release 2

Purpose: Disable Interrupts

To return the previous value of the *Status* register and disable interrupts. If DI is specified without an argument, GPR r0 is implied, which discards the previous value of the *Status* register.

Description: $\text{GPR}[\text{rt}] \leftarrow \text{Status}; \text{Status}_{\text{IE}} \leftarrow 0$

The current value of the *Status* register is loaded into general register *rt*. The Interrupt Enable (IE) bit in the *Status* register is then cleared.

Restrictions:

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

This operation specification is for the general interrupt enable/disable operation, with the *sc* field as a variable. The individual instructions DI and EI have a specific value for the *sc* field.

```
data ← Status
GPR[rt] ← data
StatusIE ← 0
```

Exceptions:

Coprocessor Unusable
Reserved Instruction (Release 1 implementations)

Programming Notes:

The effects of this instruction are identical to those accomplished by the sequence of reading *Status* into a GPR, clearing the IE bit, and writing the result back to *Status*. Unlike the multiple instruction sequence, however, the DI instruction cannot be aborted in the middle by an interrupt or exception.

This instruction creates an execution hazard between the change to the *Status* register and the point where the change to the interrupt enable takes effect. This hazard is cleared by the EHB, JALR.HB, JR.HB, or ERET instructions. Software must not assume that a fixed latency will clear the execution hazard.

Format: DIV *rs*, *rt*

MIPS32, removed in Release 6

Purpose: Divide Word

To divide a 32-bit signed integers.

Description: (HI, LO) \leftarrow GPR[*rs*] / GPR[*rt*]

The 32-bit word value in GPR *rs* is divided by the 32-bit value in GPR *rt*, treating both operands as signed values. The 32-bit quotient is placed into special register *LO* and the 32-bit remainder is placed into special register *HI*.

No arithmetic exception occurs under any circumstances.

Restrictions:

If the divisor in GPR *rt* is zero, the arithmetic result value is **UNPREDICTABLE**.

Availability and Compatibility:

DIV has been removed in Release 6 and has been replaced by DIV and MOD instructions that produce only quotient and remainder, respectively. Refer to the Release 6 introduced 'DIV' and 'MOD' instructions in this manual for more information. This instruction remains current for all release levels lower than Release 6 of the MIPS architecture.

Operation:

```

q ← GPR[rs]31..0 div GPR[rt]31..0
LO ← q
r ← GPR[rs]31..0 mod GPR[rt]31..0
HI ← r

```

Exceptions:

None

Programming Notes:

No arithmetic exception occurs under any circumstances. If divide-by-zero or overflow conditions are detected and some action taken, then the divide instruction is followed by additional instructions to check for a zero divisor and/or for overflow. If the divide is asynchronous then the zero-divisor check can execute in parallel with the divide. The action taken on either divide-by-zero or overflow is either a convention within the program itself, or within the system software. A possibility is to take a BREAK exception with a *code* field value to signal the problem to the system software.

As an example, the C programming language in a UNIX® environment expects division by zero to either terminate the program or execute a program-specified signal handler. C does not expect overflow to cause any exceptional condition. If the C compiler uses a divide instruction, it also emits code to test for a zero divisor and execute a BREAK instruction to inform the operating system if a zero is detected.

By default, most compilers for the MIPS architecture emits additional instructions to check for the divide-by-zero and overflow cases when this instruction is used. In many compilers, the assembler mnemonic "DIV r0, rs, rt" can be used to prevent these additional test instructions to be emitted.

In some processors the integer divide operation may proceed asynchronously and allow other CPU instructions to execute before it is complete. An attempt to read *LO* or *HI* before the results are written interlocks until the results are

ready. Asynchronous execution does not affect the program result, but offers an opportunity for performance improvement by scheduling the divide so that other instructions can execute in parallel.

Historical Perspective:

In MIPS 1 through MIPS III, if either of the two instructions preceding the divide is an MFHI or MFLO, the result of the MFHI or MFLO is **UNPREDICTABLE**. Reads of the *HI* or *LO* special register must be separated from subsequent instructions that write to them by two or more instructions. This restriction was removed in MIPS IV and MIPS32 and all subsequent levels of the architecture.

Format: DIV MOD DIVU MODU
 DIV rd,rs,rt
 MOD rd,rs,rt
 DIVU rd,rs,rt
 MODU rd,rs,rt

MIPS32 Release 6
 MIPS32 Release 6
 MIPS32 Release 6
 MIPS32 Release 6

Purpose: Divide Integers (with result to GPR)

DIV: Divide Words Signed
 MOD: Modulo Words Signed
 DIVU: Divide Words Signed
 MODU: Modulo Words Signed

Description:

DIV: $GPR[rd] \leftarrow (divide.signed(GPR[rs] \div GPR[rt]))$
 MOD: $GPR[rd] \leftarrow (modulo.signed(GPR[rs] \bmod GPR[rt]))$
 DIVU: $GPR[rd] \leftarrow (divide.unsigned(GPR[rs] \div GPR[rt]))$
 MODU: $GPR[rd] \leftarrow (modulo.unsigned(GPR[rs] \bmod GPR[rt]))$

The Release 6 divide and modulo instructions divide the operands in GPR *rs* and GPR *rt*, and place the quotient or remainder in GPR *rd*.

For each of the div/mod operator pairs DIV/MOD, DIVU/MODU, the results satisfy the equation $(A \div B) * B + (A \bmod B) = A$, where $(A \bmod B)$ has same sign as the dividend *A*, and $abs(A \bmod B) < abs(B)$. This equation uniquely defines the results.

NOTE: if the divisor *B*=0, this equation cannot be satisfied, and the result is UNPREDICTABLE. This is commonly called “truncated division”.

DIV performs a signed 32-bit integer division, and places the 32-bit quotient result in the destination register.

MOD performs a signed 32-bit integer division, and places the 32-bit remainder result in the destination register. The remainder result has the same sign as the dividend.

DIVU performs an unsigned 32-bit integer division, and places the 32-bit quotient result in the destination register.

MODU performs an unsigned 32-bit integer division, and places the 32-bit remainder result in the destination register.

Restrictions:

If the divisor in GPR *rt* is zero, the result value is UNPREDICTABLE.

Availability and Compatibility:

These instructions are introduced by and required as of Release 6.

Release 6 divide instructions have the same opcode mnemonic as the pre-Release 6 divide instructions (DIV, DIVU). The instruction encodings are different, as are the instruction semantics: the Release 6 instruction produces only the quotient, whereas the pre-Release 6 instruction produces quotient and remainder in HI/LO registers respectively, and separate modulo instructions are required to obtain the remainder.

The assembly syntax distinguishes the Release 6 from the pre-Release 6 divide instructions. For example, Release 6 “DIV rd,rs,rt” specifies 3 register operands, versus pre-Release 6 “DIV rs,rt”, which has only two register arguments, with the HI/LO registers implied. Some assemblers accept the pseudo-instruction syntax “DIV rd,rs,rt” and expand it to do “DIV rs,rt;MFHI rd”. Phrases such as “DIV with GPR output” and “DIV with HI/LO output” may be used when disambiguation is necessary.

Pre-Release 6 divide instructions that produce quotient and remainder in the HI/LO registers produce a Reserved Instruction Exception on Release 6. In the future, the instruction encoding may be reused for other instructions.

Programming Notes:

Because the divide and modulo instructions are defined to not trap if dividing by zero, it is safe to emit code that checks for zero-divide after the divide or modulo instruction.

Operation

```

DIV, MOD: if NotWordValue(GPR[rs]) then UNPREDICTABLE endif
DIV, MOD: if NotWordValue(GPR[rt]) then UNPREDICTABLE endif
DIVU, MODU: if not(zero_or_sign_extended.32(GPR[rs])) then UNPREDICTABLE endif
DIVU, MODU: if not(zero_or_sign_extended.32(GPR[rt])) then UNPREDICTABLE endif
DIV, MOD:
    s1 ← signed_word(GPR[rs])
    s2 ← signed_word(GPR[rt])
DIVU, MODU:
    s1 ← unsigned_word(GPR[rs])
    s2 ← unsigned_word(GPR[rt])

DIV, DIVU:
    quotient ← s1 div s2
MOD, MODU:
    remainder ← s1 mod s2

DIV:    GPR[rd] ← quotient
MOD:    GPR[rd] ← remainder
DIVU:   GPR[rd] ← quotient
MODU:   GPR[rd] ← remainder
/* end of instruction */

```

Exceptions:

None¹

-
1. No arithmetic exception occurs under any circumstances. Division by zero produces an UNPREDICTABLE result.

DIV.D fd, fs, ft

MIPS32

MIPS32

Purpose: Floating Point Divide

To divide FP values.

Description: $FPR[fd] \leftarrow FPR[fs] / FPR[ft]$

The value in FPR *fs* is divided by the value in FPR *ft*. The result is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operands and result are values in format *fmt*.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

Operation:

StoreFPR (fd, fmt, ValueFPR(fs, fmt) / ValueFPR(ft, fmt))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Format: DIVU *rs*, *rt*

MIPS32, removed in Release 6

Purpose: Divide Unsigned Word

To divide a 32-bit unsigned integers

Description: $(HI, LO) \leftarrow GPR[rs] / GPR[rt]$

The 32-bit word value in GPR *rs* is divided by the 32-bit value in GPR *rt*, treating both operands as unsigned values. The 32-bit quotient is placed into special register *LO* and the 32-bit remainder is placed into special register *HI*.

No arithmetic exception occurs under any circumstances.

Restrictions:

If the divisor in GPR *rt* is zero, the arithmetic result value is **UNPREDICTABLE**.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

q ← (0 || GPR[rs]31..0) div (0 || GPR[rt]31..0)
r ← (0 || GPR[rs]31..0) mod (0 || GPR[rt]31..0)
LO ← sign_extend(q31..0)
HI ← sign_extend(r31..0)

```

Exceptions:

None

Programming Notes:

Pre-Release 6 instruction DIV has been removed in Release 6 and has been replaced by DIV and MOD instructions that produce only quotient and remainder, respectively. Refer to the Release 6 introduced ‘DIV’ and ‘MOD’ instructions in this manual for more information. This instruction remains current for all release levels lower than Release 6 of the MIPS architecture.

See “Programming Notes” for the [DIV](#) instruction.

Historical Perspective:

In MIPS 1 through MIPS III, if either of the two instructions preceding the divide is an MFHI or MFLO, the result of the MFHI or MFLO is UNPREDICTABLE. Reads of the *HI* or *LO* special register must be separated from subsequent instructions that write to them by two or more instructions. This restriction was removed in MIPS IV and MIPS32 and all subsequent levels of the architecture.

6		5		5		5		5		1	2		3	

Format: DVP
DVP rt

MIPS32 Release 6
MIPS32 Release 6

Purpose: Disable Virtual Processor

To disable all virtual processors in a physical core other than the virtual processor that issued the instruction.

Description: $GPR[rt] \leftarrow VPControl$; $VPControl_{DIS} \leftarrow 1$

Disabling a virtual processor means that instruction fetch is terminated, and all outstanding instructions for the affected virtual processor(s) must be complete before the DVP itself is allowed to retire. Any outstanding events such as hardware instruction or data prefetch, or page-table walks must also be terminated.

The DVP instruction has implicit SYNC(*stype*=0) semantics but with respect to the other virtual processors in the physical core.

After all other virtual processors have been disabled, $VPControl_{DIS}$ is set. Prior to modification and if *rt* is non-zero, $VPControl$ is written to $GPR[rt]$. If DVP is specified without *rt*, then *rt* must be 0.

DVP may also take effect on a virtual processor that has executed a WAIT or a PAUSE instruction. If a virtual processor has executed a WAIT instruction, then it cannot resume execution on an interrupt until an EVP has been executed. If the EVP is executed before the interrupt arrives, then the virtual processor resumes in a state as if the DVP had not been executed, that is, it waits for the interrupt.

If a virtual processor has executed a PAUSE instruction, then it cannot resume execution until an EVP has been executed, even if LLbit is cleared. If an EVP is executed before the LLbit is cleared, then the virtual processor resumes in a state as if the DVP has not been executed, that is, it waits for the LLbit to clear.

The execution of a DVP must be followed by the execution of an EVP. The execution of an EVP causes execution to resume immediately—where applicable—on all other virtual processors, as if the DVP had not been executed. The execution is completely restorable after the EVP. If an event occurs in between the DVP and EVP that renders state of the virtual processor UNPREDICTABLE (such as power-gating), then the effect of EVP is UNPREDICTABLE.

DVP may only take effect if $VPControl_{DIS}=0$. Otherwise it is treated as a NOP instruction.

If a virtual processor is disabled due to a DVP, then interrupts are also disabled for the virtual processor, that is, logically $Status_{IE}=0$. $Status_{IE}$ for the target virtual processors though is not cleared though as software cannot access state on the virtual processors that have been disabled. The virtual processor which executes the DVP however continues to be interruptible.

In an implementation, the ability of a virtual processor to execute instructions may also be under control external to the physical core which contains the virtual processor. If disabled by DVP, a virtual processor must not resume fetch in response to the assertion of this external signal to enable fetch. Conversely, if fetch is disabled by such external control, then execution of EVP will not cause fetch to resume at a target virtual processor for which the control is deasserted.

This instruction never executes speculatively. It must be the oldest unretired instruction to take effect.

This instruction is only available in Release 6 implementations. For implementations that do not support multi-threading ($Config5_{VP}=0$), this instruction must be treated as a NOP instruction.

Restrictions:

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

In implementations prior to Release 6 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

The pseudo-code below assumes that the DVP is executed by virtual processor 0, while the target virtual processor is numbered 'n', where n is each of all remaining virtual processors.

```

if (VPControlDIS = 0)

    // Pseudo-code in italics provides recommended action wrt other VPs
    disable_fetch(VPn) {
        if PAUSE(VPn) retires prior or at disable event
            then VPn execution is not resumed if LLbit is cleared prior to EVP
    }
    disable_interrupt(VPn) {
        if WAIT(VPn) retires prior or at disable event
            then interrupts are ignored by VPn until EVP
    }
    // DVP0 not retired until instructions for VPn completed
    while (VPn outstanding instruction)
        DVP0 unretired
    endwhile

endif

data ← VPControl
GPR[rt] ← data
VPControlDIS ← 1

```

Exceptions:

Coprocessor Unusable

Reserved Instruction (pre-Release 6 implementations)

Programming Notes:

DVP may disable execution in the target virtual processor regardless of the operating mode - kernel, supervisor, user. Kernel software may also be in a critical region, or in a high-priority interrupt handler when the disable occurs. Since the instruction is itself privileged, such events are considered acceptable.

Before executing an EVP in a DVP/EVP pair, software should first read VPControl_{DIS}, returned by DVP, to determine whether the virtual processors are already disabled. If so, the DVP/EVP sequence should be abandoned. This step allows software to safely nest DVP/EVP pairs.

Privileged software may use DVP/EVP to disable virtual processors on a core, such as for the purpose of doing a cache flush without interference from other processes in a system with multiple virtual processors or physical cores.

DVP (and EVP) may be used in other cases such as for power-savings or changing state that is applicable to all virtual processors in a core, such as virtual processor scheduling priority, as described below :

```
ll t0 0(a0)
dvp    // disable all other virtual processors
pause  // wait for LLbit to clear
evp    // enable all othe virtual processors

ll t0 0(a0)
dvp    // disable all other virtual processors
<change core-wide state>
evp    // enable all othe virtual processors
```

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL 000000	0 00000	0 00000	0 00000	0 00000	3 00011	SLL 000000					
6	5	5	5	5	5	6					

Format: EHB

Assembly Idiom MIPS32 Release 2

Purpose: Execution Hazard Barrier

To stop instruction execution until all execution hazards have been cleared.

Description:

EHB is used to denote execution hazard barrier. The actual instruction is interpreted by the hardware as SLL r0, r0, 3. This instruction alters the instruction issue behavior on a pipelined processor by stopping execution until all execution hazards have been cleared. Other than those that might be created as a consequence of setting *Status_{CU0}*, there are no execution hazards visible to an unprivileged program running in User Mode. All execution hazards created by previous instructions are cleared for instructions executed immediately following the EHB, even if the EHB is executed in the delay slot of a branch or jump. The EHB instruction does not clear instruction hazards—such hazards are cleared by the JALR.HB, JR.HB, and ERET instructions.

Restrictions:

None

Operation:

```
ClearExecutionHazards()
```

Exceptions:

None

Programming Notes:

In MIPS32 Release 2 implementations, this instruction resolves all execution hazards. On a superscalar processor, EHB alters the instruction issue behavior in a manner identical to SSNOP. For backward compatibility with Release 1 implementations, the last of a sequence of SSNOPs can be replaced by an EHB. In Release 1 implementations, the EHB will be treated as an SSNOP, thereby preserving the semantics of the sequence. In Release 2 implementations, replacing the final SSNOP with an EHB should have no performance effect because a properly sized sequence of SSNOPs will have already cleared the hazard. As EHB becomes the standard in MIPS implementations, the previous SSNOPs can be removed, leaving only the EHB.

31	26	25	21	20	16	15	11	10	6	5	4	3	2	0
COP0 0100 00		MFMC0 01 011		rt		12 0110 0		0 000 00		sc 1	0 0 0	0 000		
6		5		5		5		5		1	2	3		

Format: EI
EI rt

MIPS32 Release 2
MIPS32 Release 2

Purpose: Enable Interrupts

To return the previous value of the *Status* register and enable interrupts. If EI is specified without an argument, GPR r0 is implied, which discards the previous value of the *Status* register.

Description: $\text{GPR}[\text{rt}] \leftarrow \text{Status}; \text{Status}_{\text{IE}} \leftarrow 1$

The current value of the *Status* register is loaded into general register *rt*. The Interrupt Enable (*IE*) bit in the *Status* register is then set.

Restrictions:

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

This operation specification is for the general interrupt enable/disable operation, with the *sc* field as a variable. The individual instructions DI and EI have a specific value for the *sc* field.

```
data ← Status
GPR[rt] ← data
StatusIE ← 1
```

Exceptions:

Coprocessor Unusable
Reserved Instruction (Release 1 implementations)

Programming Notes:

The effects of this instruction are identical to those accomplished by the sequence of reading *Status* into a GPR, setting the *IE* bit, and writing the result back to *Status*. Unlike the multiple instruction sequence, however, the EI instruction cannot be aborted in the middle by an interrupt or exception.

This instruction creates an execution hazard between the change to the *Status* register and the point where the change to the interrupt enable takes effect. This hazard is cleared by the EHB, JALR.HB, JR.HB, or ERET instructions. Software must not assume that a fixed latency will clear the execution hazard.

31	26	25	24		6	5	0
COP0 010000	CO 1	0 000 0000 0000 0000 0000					ERET 011000
6	1	19					6

Format: ERET

MIPS32

Purpose: Exception Return

To return from interrupt, exception, or error trap.

Description:

ERET clears execution and instruction hazards, conditionally restores $SRSCtl_{CSS}$ from $SRSCtl_{PSS}$ in a Release 2 implementation, and returns to the interrupted instruction at the completion of interrupt, exception, or error processing. ERET does not execute the next instruction (that is, it has no delay slot).

Restrictions:

Pre-Release 6: The operation of the processor is **UNDEFINED** if an ERET is executed in the delay slot of a branch or jump instruction.

Release 6: Implementations are required to signal a Reserved Instruction Exception if ERET is encountered in the delay slot or forbidden slot of a branch or jump instruction.

An ERET placed between an LL and SC instruction will always cause the SC to fail.

ERET implements a software barrier that resolves all execution and instruction hazards created by Coprocessor 0 state changes (for Release 2 implementations, refer to the SYNCI instruction for additional information on resolving instruction hazards created by writing the instruction stream). The effects of this barrier are seen starting with the instruction fetch and decode of the instruction at the PC to which the ERET returns.

In a Release 2 implementation, ERET does not restore $SRSCtl_{CSS}$ from $SRSCtl_{PSS}$ if $Status_{BEV} = 1$, or if $Status_{ERL} = 1$ because any exception that sets $Status_{ERL}$ to 1 (Reset, Soft Reset, NMI, or cache error) does not save $SRSCtl_{CSS}$ in $SRSCtl_{PSS}$. If software sets $Status_{ERL}$ to 1, it must be aware of the operation of an ERET that may be subsequently executed.

Operation:

```

if StatusERL = 1 then
    temp ← ErrorEPC
    StatusERL ← 0
else
    temp ← EPC
    StatusEXL ← 0
    if (ArchitectureRevision ≥ 2) and (SRSCtlHSS > 0) and (StatusBEV = 0) then
        SRSCtlCSS ← SRSCtlPSS
    endif
endif
if IsMIPS16Implemented() | (Config3ISA > 0) then
    PC ← temp31..1 || 0
    ISAMode ← temp0
else
    PC ← temp
endif
LLbit ← 0
ClearHazards()

```

Exceptions:

Coprocessor Unusable Exception

31	26	25	24		6	5	0
COP0 010000	CO 1	0 000 0000 0000 0000 000				1	ERET 011000
6	1	18				1	6

Format: ERETNC

MIPS32 Release 5

Purpose: Exception Return No Clear

To return from interrupt, exception, or error trap without clearing the LLbit.

Description:

ERETNC clears execution and instruction hazards, conditionally restores $SRSCtl_{CSS}$ from $SRSCtl_{PSS}$ when implemented, and returns to the interrupted instruction at the completion of interrupt, exception, or error processing. ERETNC does not execute the next instruction (i.e., it has no delay slot).

ERETNC is identical to ERET except that an ERETNC will not clear the LLbit that is set by execution of an LL instruction, and thus when placed between an LL and SC sequence, will never cause the SC to fail.

An ERET must continue to be used by default in interrupt and exception processing handlers. The handler may have accessed a synchronizable block of memory common to code that is atomically accessing the memory, and where the code caused the exception or was interrupted. Similarly, a process context-swap must also continue to use an ERET in order to avoid a possible false success on execution of SC in the restored context.

Multiprocessor systems with non-coherent cores (i.e., without hardware coherence snooping) should also continue to use ERET, because it is the responsibility of software to maintain data coherence in the system.

An ERETNC is useful in cases where interrupt/exception handlers and kernel code involved in a process context-swap can guarantee no interference in accessing synchronizable memory across different contexts. ERETNC can also be used in an OS-level debugger to single-step through code for debug purposes, avoiding the false clearing of the LLbit and thus failure of an LL and SC sequence in single-stepped code.

Software can detect the presence of ERETNC by reading $Config5_{LLB}$.

Restrictions:

Release 6 implementations are required to signal a Reserved Instruction Exception if ERETNC is executed in the delay slot or forbidden slot of a branch or jump instruction.

ERETNC implements a software barrier that resolves all execution and instruction hazards created by Coprocessor 0 state changes. (For Release 2 implementations, refer to the SYNCI instruction for additional information on resolving instruction hazards created by writing the instruction stream.) The effects of this barrier are seen starting with the instruction fetch and decode of the instruction in the PC to which the ERETNC returns.

Operation:

```

if StatusERL = 1 then
    temp ← ErrorEPC
    StatusERL ← 0
else
    temp ← EPC
    StatusEXL ← 0
    if (ArchitectureRevision ≥ 2) and (SRSCtlHSS > 0) and (StatusBEV = 0) then
        SRSCtlCSS ← SRSCtlPSS
    endif
endif
if IsMIPS16Implemented() | (Config3ISA > 0) then

```

```
    PC ← temp31..1 || 0
    ISAMode ← temp0
else
    PC ← temp
endif
ClearHazards()
```

Exceptions:

Coprocessor Unusable Exception

31	26	25	21	20	16	15	11	10	6	5	4	3	2	0
COP0 010000			MFMC0 01011		rt		0 00000		0 00000		sc 0	0 00	4 100	
6			5		5		5		5		1	2	3	

Format: EVP
EVP rt

MIPS32 Release 6
MIPS32 Release 6

Purpose: Enable Virtual Processor

To enable all virtual processors in a physical core other than the virtual processor that issued the instruction.

Description: $GPR[rt] \leftarrow VPControl$; $VPControl_{DIS} \leftarrow 0$

Enabling a virtual processor means that instruction fetch is resumed.

After all other virtual processors have been enabled, $VPControl_{DIS}$ is cleared. Prior to modification, if rt is non-zero, $VPControl$ is written to $GPR[rt]$. If EVP is specified without rt , then rt must be 0.

See the DVP instruction to learn about the behavior of EVP in the context of WAIT/PAUSE/external-control (“DVP” on page 171).

The execution of a DVP must be followed by the execution of an EVP. The execution of an EVP causes execution to resume immediately, *where applicable*, on all other virtual processors, as if the DVP had not been executed, that is, execution is completely restorable after the EVP. On the other hand, if an event occurs in between the DVP and EVP that renders state of the virtual processor UNPREDICTABLE (such as power-gating), then the effect of EVP is UNPREDICTABLE.

EVP may only take effect if $VPControl_{DIS}=1$. Otherwise it is treated as a NOP

This instruction never executes speculatively. It must be the oldest unretired instruction to take effect.

This instruction is only available in Release 6 implementations. For implementations that do not support multi-threading ($Config5_{VP}=0$), this instruction must be treated as a NOP instruction.

Restrictions:

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

In implementations prior to Release 6 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

The pseudo-code below assumes that the EVP is executed by virtual processor 0, while the target virtual processor is numbered ‘n’, where n is each of all remaining virtual processors.

```

if (VPControlDIS = 1)

    // Pseudo-code in italics provides recommended action wrt other VPs
    enable_fetch(VPn) {
        if PAUSE(VPn) retires prior or at disable event
            then VPn execution is not resumed if LLbit is cleared prior to EVP
    }
    enable_interrupt(VPn) {
        if WAIT(VPn) retires prior or at disable event
            then interrupts are ignored by VPn until EVP
    }

```

```

    }

    endif

    data ← VPControl
    GPR[rt] ← data
    VPControlDIS ← 0

```

Exceptions:

Coprocessor Unusable
Reserved Instruction (pre-Release 6 implementations)

Programming Notes:

Before executing an EVP in a DVP/EVP pair, software should first read `VPControlDIS`, returned by DVP, to determine whether the virtual processors are already disabled. If so, the DVP/EVP sequence should be abandoned. This step allows software to safely nest DVP/EVP pairs.

Privileged software may use DVP/EVP to disable virtual processors on a core, such as for the purpose of doing a cache flush without interference from other processes in a system with multiple virtual processors or physical cores.

DVP (and EVP) may be used in other cases such as for power-savings or changing state that is applicable to all virtual processors in a core, such as virtual processor scheduling priority, as described below:

```

ll t0 0(a0)
dvp    // disable all other virtual processors
pause  // wait for LLbit to clear
evp    // enable all othe virtual processors

ll t0 0(a0)
dvp    // disable all other virtual processors
<change core-wide state>
evp    // enable all othe virtual processors

```

Format: EXT *rt*, *rs*, *pos*, *size*

MIPS32 Release 2

Purpose: Extract Bit Field

To extract a bit field from GPR *rs* and store it right-justified into GPR *rt*.

Description: $\text{GPR}[rt] \leftarrow \text{ExtractField}(\text{GPR}[rs], \text{msbd}, \text{lsb})$

The bit field starting at bit *pos* and extending for *size* bits is extracted from GPR *rs* and stored zero-extended and right-justified in GPR *rt*. The assembly language arguments *pos* and *size* are converted by the assembler to the instruction fields *msbd* (the most significant bit of the destination field in GPR *rt*), in instruction bits **15..11**, and *lsb* (least significant bit of the source field in GPR *rs*), in instruction bits **10..6**, as follows:

```
msbd ← size-1
lsb ← pos
```

The values of *pos* and *size* must satisfy all of the following relations:

```
0 ≤ pos < 32
0 < size ≤ 32
0 < pos+size ≤ 32
```

Figure 3-9 shows the symbolic operation of the instruction.

Figure 3.5 Operation of the EXT Instruction

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

The operation is **UNPREDICTABLE** if $\text{lsb} + \text{msbd} > 31$.

Operation:

```
if (lsb + msbd) > 31 then
    UNPREDICTABLE
endif
temp ← 032 - (msbd+1) || GPR[rs]msbd+lsb..lsb
```

$\text{GPR}[\text{rt}] \leftarrow \text{temp}$

Exceptions:

Reserved Instruction

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt					0 00000	fs			fd	FLOOR.L 001011
6	5					5	5			5	6

Format: FLOOR.L.fmt
 FLOOR.L.S fd, fs
 FLOOR.L.D fd, fs

MIPS32 Release 2
MIPS32 Release 2

Purpose: Floating Point Floor Convert to Long Fixed Point

To convert an FP value to 64-bit fixed point, rounding down

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

The value in FPR *fs*, in format *fmt*, is converted to a value in 64-bit long fixed point format and rounded toward \geq (rounding mode 3). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{63} to $2^{63}-1$, the result cannot be represented correctly, an IEEE Invalid Operation condition exists, and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation Enable bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, $2^{63}-1$, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs: *fs* for type *fmt* and *fd* for long fixed point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Operation:

$\text{StoreFPR}(fd, L, \text{ConvertFmt}(\text{ValueFPR}(fs, fmt), fmt, L))$

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact

31	26	25	21	20	16	15	11	10	6	5	0

FLOOR.W.S fd, fs

FLOOR.W.D fd, fs

MIPS32

MIPS32

Purpose: Floating Point Floor Convert to Word Fixed Point

To convert an FP value to 32-bit fixed point, rounding down

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

The value in FPR *fs*, in format *fmt*, is converted to a value in 32-bit word fixed point format and rounded toward \rightarrow (rounding mode 3). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{31} to $2^{31}-1$, the result cannot be represented correctly, an IEEE Invalid Operation condition exists, and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, $2^{31}-1$, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs: *fs* for type *fmt* and *fd* for word fixed point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

`StoreFPR(fd, W, ConvertFmt(ValueFPR(fs, fmt), fmt, W))`

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact

Format: INS *rt*, *rs*, *pos*, *size*

MIPS32 Release 2

Purpose: Insert Bit Field

To merge a right-justified bit field from GPR *rs* into a specified field in GPR *rt*.

Description: $\text{GPR}[rt] \leftarrow \text{InsertField}(\text{GPR}[rt], \text{GPR}[rs], \text{msb}, \text{lsb})$

The right-most *size* bits from GPR *rs* are merged into the value from GPR *rt* starting at bit position *pos*. The result is placed back in GPR *rt*. The assembly language arguments *pos* and *size* are converted by the assembler to the instruction fields *msb* (the most significant bit of the field), in instruction bits 15..11, and *lsb* (least significant bit of the field), in instruction bits 10..6, as follows:

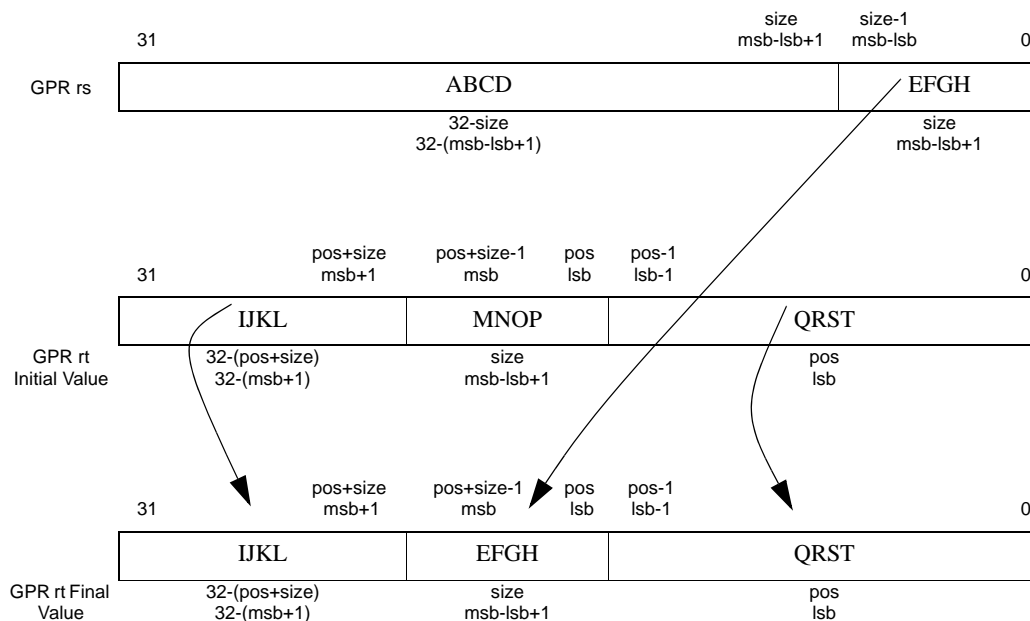

$\text{msb} \leftarrow \text{pos} + \text{size} - 1$
 $\text{lsb} \leftarrow \text{pos}$

The values of *pos* and *size* must satisfy all of the following relations:

$0 \leq \text{pos} < 32$
 $0 < \text{size} \leq 32$
 $0 < \text{pos} + \text{size} \leq 32$

Figure 3-10 shows the symbolic operation of the instruction.

Figure 3.6 Operation of the INS Instruction

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Except-

tion.

The operation is **UNPREDICTABLE** if $lsb > msb$.

Operation:

```

    if lsb > msb) then
        UNPREDICTABLE
    endif
    GPR[rt] ← GPR[rt]31..msb+1 || GPR[rs]msb-lsb..0 || GPR[rt]lsb-1..0

```

Exceptions:

Reserved Instruction

Format: J target

MIPS32

Purpose: Jump

To branch within the current 256 MB-aligned region.

Description:

This is a PC-region branch (not PC-relative); the effective target address is in the “current” 256 MB-aligned region. The low 28 bits of the target address is the *instr_index* field shifted left 2bits. The remaining upper bits are the corresponding bits of the address of the instruction in the delay slot (not the branch itself).

Jump to the effective target address. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself.

Restrictions:

Control Transfer Instructions (CTIs) should not be placed in branch delay slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See [4.1.3 “Jump and Branch Instructions” on page 86](#) in Volume I for detailed discussion of correctness and performance issues.

Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Operation:

I:
I+1: $PC \leftarrow PC_{GPREN-1..28} || instr_index || 0^2$

Exceptions:

None

Programming Notes:

Forming the branch target address by catenating PC and index bits rather than adding a signed offset to the PC is an advantage if all program code addresses fit into a 256MB region aligned on a 256MB boundary. It allows a branch from anywhere in the region to anywhere in the region, an action not allowed by a signed relative offset.

This definition creates the following boundary case: When the jump instruction is in the last word of a 256MB region, it can branch only to the following 256MB region containing the branch delay slot.

Format: JAL target

MIPS32

Purpose: Jump and Link

To execute a procedure call within the current 256MB-aligned region.

Description:

Place the return address link in GPR 31. The return link is the address of the second instruction following the branch, at which location execution continues after a procedure call.

This is a PC-region branch (not PC-relative); the effective target address is in the “current” 256MB-aligned region. The low 28 bits of the target address is the *instr_index* field shifted left 2bits. The remaining upper bits are the corresponding bits of the address of the instruction in the delay slot (not the branch itself).

Jump to the effective target address. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself.

Restrictions:

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Operation:

I: GPR[31] ← PC + 8
I+1: PC ← PC_{GPRLEN-1..28} || instr_index || 0²

Exceptions:

None

Programming Notes:

Forming the branch target address by catenating PC and index bits rather than adding a signed offset to the PC is an advantage if all program code addresses fit into a 256MB region aligned on a 256MB boundary. It allows a branch from anywhere in the region to anywhere in the region, an action not allowed by a signed relative offset.

This definition creates the following boundary case: When the branch instruction is in the last word of a 256MB region, it can branch only to the following 256MB region containing the branch delay slot.

pre-Release 6

31	26	25	21	20	16	15	11	10	6	5	0

6	5	5	5	5	6						

Release 6

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL 000000	rs	0 00000	rd rd ≠ 00000	hint	JALR 001001						
6	5	5	5	5	6						

Format: JALR rs (rd = 31 implied)
JALR rd, rs

MIPS32
MIPS32

Purpose: Jump and Link Register

To execute a procedure call to an instruction address in a register

Description: $GPR[rd] \leftarrow return_addr$, $PC \leftarrow GPR[rs]$

Place the return address link in GPR *rd*. The return link is the address of the second instruction following the branch, where execution continues after a procedure call.

For processors that do not implement the MIPS16e ASE nor microMIPS32/64 ISA:

- Jump to the effective target address in GPR *rs*. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one.

For processors that do implement the MIPS16e ASE or microMIPS32/64 ISA:

- Jump to the effective target address in GPR *rs*. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself. Set the *ISA Mode* bit to the value in GPR *rs* bit 0. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one.

In release 1 of the architecture, the only defined hint field value is 0, which sets default handling of JALR. In Release 2 of the architecture, bit 10 of the hint field is used to encode a hazard barrier. See the [JALR.HB](#) instruction description for additional information.

Availability and Compatibility:

Release 6 maps JR and JR.HB to JALR and JALR.HB with rd = 0:

Pre-Release 6, JR and JALR were distinct instructions, both with primary opcode SPECIAL, but with distinct function codes.

Release 6: JR is defined to be JALR with the destination register specifier *rd* set to 0. The primary opcode and function field are the same for JR and JALR. The pre-Release 6 instruction encoding is removed in Release 6.

Similarly, for JALR.HB, which continues to correspond to JALR with bit 4 of the hint field (bit 10 of the instruction) set to 1.

Release 6 assemblers should accept the JR and JR.HB mnemonics, mapping them to the Release 6 instruction encodings.

Restrictions:

This control transfer instruction has a delay slot.

Jump-and-Link Restartability: Register specifiers *rs* and *rd* must not be equal, because such an instruction does not have the same effect when reexecuted. The result of executing such an instruction is **UNPREDICTABLE**. This restriction permits an exception handler to resume execution by re-executing the branch when an exception occurs in the delay slot.

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Restrictions Related to Multiple Instruction Sets: This instruction can change the active instruction set, if more than one instruction set is implemented.

If only one instruction set is implemented, then the effective target address must obey the alignment rules of the instruction set. If multiple instruction sets are implemented, the effective target address must obey the alignment rules of the intended instruction set of the target address as specified by the bit 0 of GPR *rs*.

For processors that do not implement the microMIPS32/64 ISA, the effective target address in GPR *rs* must be naturally-aligned. For processors that do not implement the MIPS16e ASE nor microMIPS32/64 ISA, if either of the two least-significant bits are not zero, an Address Error exception occurs when the branch target is subsequently fetched as an instruction.

For processors that do implement the MIPS16e ASE or microMIPS32/64 ISA, if target ISAMode bit is 0 (GPR *rs* bit 0) is zero and bit 1 is one, an Address Error exception occurs when the jump target is subsequently fetched as an instruction.

Operation:

```

I: temp ← GPR[rs]
   GPR[rd] ← PC + 8
I+1: if Config1_CA = 0 then
    PC ← temp
    else
    PC ← temp_GPREN-1..1 || 0
    ISAMode ← temp_0
    endif

```

Exceptions:

None

Programming Notes:

This branch-and-link instruction that can select a register for the return link; other link instructions use GPR 31. The default register for GPR *rd*, if omitted in the assembly language instruction, is GPR 31.

pre-Release 6:

31	26	25	21	20	16	15	11	10	9	6	5	0
SPECIAL 000000	rs					0 00000	rd			1	Any other legal hint value	JALR 001001
6	5					5	5			1	4	6

Release 6:

31	26	25	21	20	16	15	11	10	9	6	5	0
SPECIAL 000000	rs					0 00000	rd rd ≠ 00000			1	Any other legal hint value	JALR 001001
6	5					5	5			1	4	6

Format: JALR.HB rs (rd = 31 implied)
JALR.HB rd, rs

MIPS32 Release 2
MIPS32 Release 2

Purpose: Jump and Link Register with Hazard Barrier

To execute a procedure call to an instruction address in a register and clear all execution and instruction hazards

Description: $GPR[rd] \leftarrow return_addr$, $PC \leftarrow GPR[rs]$, clear execution and instruction hazards

Place the return address link in GPR *rd*. The return link is the address of the second instruction following the branch, where execution continues after a procedure call.

For processors that do not implement the MIPS16 ASE nor microMIPS32/64 ISA:

- Jump to the effective target address in GPR *rs*. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one.

For processors that do implement the MIPS16 ASE or microMIPS32/64 ISA:

- Jump to the effective target address in GPR *rs*. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself. Set the *ISA Mode* bit to the value in GPR *rs* bit 0. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one.

JALR.HB implements a software barrier that resolves all execution and instruction hazards created by Coprocessor 0 state changes (for Release 2 implementations, refer to the SYNCI instruction for additional information on resolving instruction hazards created by writing the instruction stream). The effects of this barrier are seen starting with the instruction fetch and decode of the instruction at the PC to which the JALR.HB instruction jumps. An equivalent barrier is also implemented by the ERET instruction, but that instruction is only available if access to Coprocessor 0 is enabled, whereas JALR.HB is legal in all operating modes.

This instruction clears both execution and instruction hazards. Refer to the [EHB](#) instruction description for the method of clearing execution hazards alone.

JALR.HB uses bit 10 of the instruction (the upper bit of the hint field) to denote the hazard barrier operation.

Availability and Compatibility:

Release 6 maps JR and JR.HB to JALR and JALR.HB with rd = 0:

Pre-Release 6, JR and JALR were distinct instructions, both with primary opcode SPECIAL, but with distinct function codes.

Release 6: JR is defined to be JALR with the destination register specifier *rd* set to 0. The primary opcode and func-

tion field are the same for JR and JALR. The pre-Release 6 instruction encoding is removed in Release 6.

Similarly, for JALR.HB, which continues to correspond to JALR with bit 4 of the hint field (bit 10 of the instruction) set to 1.

Release 6 assemblers should accept the JR and JR.HB mnemonics, mapping them to the Release 6 instruction encodings.

Restrictions:

This control transfer instruction has a delay slot.

JALR.HB does not clear hazards created by any instruction that is executed in the delay slot of the JALR.HB. Only hazards created by instructions executed before the JALR.HB are cleared by the JALR.HB.

After modifying an instruction stream mapping or writing to the instruction stream, execution of those instructions has **UNPREDICTABLE** behavior until the instruction hazard has been cleared with JALR.HB, JR.HB, ERET, or DERET. Further, the operation is **UNPREDICTABLE** if the mapping of the current instruction stream is modified.

Jump-and-Link Restartability: Register specifiers *rs* and *rd* must not be equal, because such an instruction does not have the same effect when reexecuted. The result of executing such an instruction is **UNPREDICTABLE**. This restriction permits an exception handler to resume execution by re-executing the branch when an exception occurs in the delay slot.

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Restrictions Related to Multiple Instruction Sets: This instruction can change the active instruction set, if more than one instruction set is implemented.

If only one instruction set is implemented, then the effective target address must obey the alignment rules of the instruction set. If multiple instruction sets are implemented, the effective target address must obey the alignment rules of the intended instruction set of the target address as specified by the bit 0 or GPR *rs*.

For processors that do not implement the microMIPS32/64 ISA, the effective target address in GPR *rs* must be naturally-aligned. For processors that do not implement the MIPS16 ASE nor microMIPS32/64 ISA, if either of the two least-significant bits are not zero, an Address Error exception occurs when the branch target is subsequently fetched as an instruction.

For processors that do implement the MIPS16 ASE or microMIPS32/64 ISA, if bit 0 is zero and bit 1 is one, an Address Error exception occurs when the jump target is subsequently fetched as an instruction.

Operation:

```

I: temp ← GPR[rs]
   GPR[rd] ← PC + 8
I+1: if Config1CA = 0 then
    PC ← temp
  else
    PC ← tempGPREN-1..1 || 0
    ISAMode ← temp0
  endif
  ClearHazards()

```

Exceptions:

None

Programming Notes:

This branch-and-link instruction can select a register for the return link; other link instructions use GPR 31. The default register for GPR *rd*, if omitted in the assembly language instruction, is GPR 31.

Release 6 JR.HB *rs* is implemented as JALR.HB *r0, rs*, i.e. as JALR.HB with the destination set to the zero register, *r0*.

This instruction implements the final step in clearing execution and instruction hazards before execution continues. A hazard is created when a Coprocessor 0 or TLB write affects execution or the mapping of the instruction stream, or after a write to the instruction stream. When such a situation exists, software must explicitly indicate to hardware that the hazard should be cleared. Execution hazards alone can be cleared with the EHB instruction. Instruction hazards can only be cleared with a JR.HB, JALR.HB, or ERET instruction. These instructions cause hardware to clear the hazard before the instruction at the target of the jump is fetched. Note that because these instructions are encoded as jumps, the process of clearing an instruction hazard can often be included as part of a call (JALR) or return (JR) sequence, by simply replacing the original instructions with the HB equivalent.

Example: Clearing hazards due to an ASID change

```
/*
 * Code used to modify ASID and call a routine with the new
 * mapping established.
 *
 * a0 = New ASID to establish
 * a1 = Address of the routine to call
 */
mfc0    v0, C0_EntryHi      /* Read current ASID */
li      v1, ~M_EntryHiASID /* Get negative mask for field */
and     v0, v0, v1          /* Clear out current ASID value */
or      v0, v0, a0          /* OR in new ASID value */
mtc0    v0, C0_EntryHi      /* Rewrite EntryHi with new ASID */
jalr.hb a1                  /* Call routine, clearing the hazard */
nop
```

Format: JALX target

MIPS32 with (microMIPS32 or MIPS16e), removed in Release 6

Purpose: Jump and Link Exchange

To execute a procedure call within the current 256 MB-aligned region and change the *ISA Mode* from MIPS32 to microMIPS32 or MIPS16e.

Description:

Place the return address link in GPR 31. The return link is the address of the second instruction following the branch, at which location execution continues after a procedure call. The value stored in GPR 31 bit 0 reflects the current value of the *ISA Mode* bit.

This is a PC-region branch (not PC-relative); the effective target address is in the “current” 256 MB-aligned region. The low 28 bits of the target address is the *instr_index* field shifted left 2 bits. The remaining upper bits are the corresponding bits of the address of the instruction in the delay slot (not the branch itself).

Jump to the effective target address, toggling the *ISA Mode* bit. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself.

Restrictions:

This instruction only supports 32-bit aligned branch target addresses.

This control transfer instruction has a delay slot.

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Availability and Compatibility:

If the microMIPS base architecture is not implemented and the MIPS16e ASE is not implemented, a Reserved Instruction Exception is initiated.

The JALX instruction has been removed in Release 6. Pre-Release 6 code using JALX cannot run on Release 6 by trap-and-emulate. Equivalent functionality is provided by the JIALC instruction added by Release 6.

Operation:

```

I:    GPR[31] ← PC + 8
I+1:  PC ← PCGPRLEN-1..28 || instr_index || 02
      ISAMode ← (not ISAMode)

```

Exceptions:

None

Programming Notes:

Forming the branch target address by concatenating PC and index bits rather than adding a signed offset to the PC is an advantage if all program code addresses fit into a 256 MB region aligned on a 256 MB boundary. It allows a branch from anywhere in the region to anywhere in the region, an action not allowed by a signed relative offset.

This definition creates the following boundary case: When the branch instruction is in the last word of a 256 MB region, it can branch only to the following 256 MB region containing the branch delay slot.

Format: JIALC rt, offset

MIPS32 Release 6

Purpose: Jump Indexed and Link, Compact

Description: $GPR[31] \leftarrow PC+4$, $PC \leftarrow (GPR[rt] + \text{sign_extend}(\text{offset}))$

The branch target is formed by sign extending the offset field of the instruction and adding it to the contents of GPR rt.

The offset is NOT shifted, that is, each bit of the offset is added to the corresponding bit of the GPR.

Places the return address link in GPR 31. The return link is the address of the following instruction, where execution continues after a procedure call returns.

Restrictions:

This instruction is an unconditional, always taken, compact jump, and hence has neither a Delay Slot nor a Forbidden Slot. The instruction after the jump is NOT executed.

Availability and Compatibility:

This instruction is introduced by and required as of Release 6.

Release 6 instructions JIALC and BNEZC differ only in the rs field, instruction bits 21-25. JIALC and BNEZC occupy the same encoding as pre-Release 6 instruction encoding SDC2, which is removed in Release 6.¹

Exceptions:

None²

Operation:

$$GPR[31] \leftarrow PC + 4$$

$$PC \leftarrow (GPR[rt] + \text{sign_extend}(\text{target_offset}))$$

Programming Notes:

JIALC does NOT shift the offset before adding it the register. This can be used to eliminate tags in the least significant bits that would otherwise produce misalignment. It also allows JIALC to be used as a substitute for the JALX instruction, removed in Release 6, where the lower bits of the target PC, formed by the addition of GPR[rt] and the unshifted offset, specify the target ISAmode.

1. Release 6 changes the encoding of instructions such as LWC2, SWC2, LDC2, and SDC2: for example, the pre-Release 6 encoding SWC2 is removed, and Release 6 encoding SWC2 is added. Similarly for LWC2, SDC2, and LDC2.
2. Except for possible Reserved Instruction Exception if used in a Forbidden Slot, true of these and most other control transfer instructions (CTIs)

Format: JIC rt, offset

MIPS32 Release 6

Purpose: Jump Indexed, Compact

Description: $PC \leftarrow (GPR[rt] + \text{sign_extend}(\text{offset}))$

The branch target is formed by sign extending the offset field of the instruction and adding it to the contents of GPR rt.

The offset is NOT shifted, that is, each bit of the offset is added to the corresponding of the GPR.

Restrictions:

This instruction is an unconditional, always taken, compact jump, and hence has neither a Delay Slot nor a Forbidden Slot. The instruction after the jump is NOT executed.

Availability and Compatibility:

This instruction is introduced by and required as of Release 6.

Release 6 instructions JIC and BEQZC differ only in the rs field. JIC and BEQZC occupy the same encoding as pre-Release 6 instruction LDC2, which is removed in Release 6¹.

Exceptions:

None²

Operation:

$PC \leftarrow (GPR[rt] + \text{sign_extend}(\text{target_offset}))$

Programming Notes:

JIC does NOT shift the offset before adding it the register. This can be used to eliminate tags in the least significant bits that would otherwise produce misalignment. It also allows JIALC to be used as a substitute for the JALX instruction, removed in Release 6, where the lower bits of the target PC, formed by the addition of GPR[rt] and the unshifted offset, specify the target ISAmode.

1. Release 6 changes the encoding of instructions such as LWC2, SWC2, LDC2, and SDC2. Similarly for LWC2, SDC2, and LDC2.
2. Except for possible Reserved Instruction Exception if used in a Forbidden Slot, true of these and most other control transfer instructions (CTIs)

pre-Release 6:

31	26	25	21	20	11	10	6	5	0
SPECIAL 000000	rs	0 00 0000 0000	hint	JR 001000					
6	5	10	5	6					

Release 6:

31	26	25	21	20	16	15	11	10	9	6	5	0
SPECIAL 000000	rs	0 00000	00000	hint	JALR 001001							
6	5	5	5	5	6							

Format: JR rs

MIPS32
Assembly idiom MIPS32 Release 6

Purpose: Jump Register

To execute a branch to an instruction address in a register

Description: $PC \leftarrow GPR[rs]$

Jump to the effective target address in GPR *rs*. Execute the instruction following the jump, in the branch delay slot, before jumping.

For processors that implement the MIPS16e ASE or microMIPS32/64 ISA, set the *ISA Mode* bit to the value in GPR *rs* bit 0. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one

Availability and Compatibility:

Release 6 maps JR and JR.HB to JALR and JALR.HB with rd = 0:

Pre-Release 6, JR and JALR were distinct instructions, both with primary opcode SPECIAL, but with distinct function codes.

Release 6: JR is defined to be JALR with the destination register specifier *rd* set to 0. The primary opcode and function field are the same for JR and JALR. The pre-Release 6 instruction encoding is removed in Release 6.

Similarly, for JALR.HB, which continues to correspond to JALR with bit 4 of the hint field (bit 10 of the instruction) set to 1.

Release 6 assemblers should accept the JR and JR.HB mnemonics, mapping them to the Release 6 instruction encodings.

Restrictions:

This control transfer instruction has a delay slot.

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See [4.1.3 “Jump and Branch Instructions” on page 86](#) in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Restrictions Related to Multiple Instruction Sets: This instruction can change the active instruction set, if more than one instruction set is implemented.

If only one instruction set is implemented, then the effective target address must obey the alignment rules of the instruction set. If multiple instruction sets are implemented, the effective target address must obey the alignment rules of the intended instruction set of the target address as specified by the bit 0 of GPR *rs*.

For processors that do not implement the microMIPS ISA, the effective target address in GPR *rs* must be naturally-aligned. For processors that do not implement the MIPS16e ASE or microMIPS ISA, if either of the two least-significant bits are not zero, an Address Error exception occurs when the branch target is subsequently fetched as an instruction.

For processors that do implement the MIPS16e ASE or microMIPS ISA, if bit 0 is zero and bit 1 is one, an Address Error exception occurs when the jump target is subsequently fetched as an instruction.

In release 1 of the architecture, the only defined hint field value is 0, which sets default handling of JR. In Release 2 of the architecture, bit 10 of the hint field is used to encode an instruction hazard barrier. See the [JR.HB](#) instruction description for additional information.

Operation:

```

I: temp ← GPR[rs]
I+1: if Config1CA = 0 then
    PC ← temp
    else
        PC ← tempGPREN-1..1 || 0
        ISAMode ← temp0
    endif

```

Exceptions:

None

Programming Notes:

Software should use the value 31 for the *rs* field of the instruction word on return from a JAL, JALR, or BGEZAL, and should use a value other than 31 for remaining uses of JR.

pre-Release 6:

31	26	25	21	20	11	10	9	6	5	0
SPECIAL 000000	rs	0 00 0000 0000	1	Any other legal hint value	JR 001000					
6	5	10	1	4	6					

Release 6:

31	26	25	21	20	16	15	11	10	9	6	5	0
SPECIAL 000000	rs	0 00000	0 00000	1	Any other legal hint value	JALR 001001						
6	5	5	5	1	4	6						

Format: JR.HB rs

MIPS32 Release 2
Assembly idiom Release 6

Purpose: Jump Register with Hazard Barrier

To execute a branch to an instruction address in a register and clear all execution and instruction hazards.

Description: $PC \leftarrow GPR[rs]$, clear execution and instruction hazards

Jump to the effective target address in GPR *rs*. Execute the instruction following the jump, in the branch delay slot, before jumping.

JR.HB implements a software barrier that resolves all execution and instruction hazards created by Coprocessor 0 state changes (for Release 2 implementations, refer to the SYNCI instruction for additional information on resolving instruction hazards created by writing the instruction stream). The effects of this barrier are seen starting with the instruction fetch and decode of the instruction at the PC to which the JR.HB instruction jumps. An equivalent barrier is also implemented by the ERET instruction, but that instruction is only available if access to Coprocessor 0 is enabled, whereas JR.HB is legal in all operating modes.

This instruction clears both execution and instruction hazards. Refer to the [EHB](#) instruction description for the method of clearing execution hazards alone.

JR.HB uses bit 10 of the instruction (the upper bit of the hint field) to denote the hazard barrier operation.

For processors that implement the MIPS16e ASE or microMIPS32/64 ISA, set the *ISA Mode* bit to the value in GPR *rs* bit 0. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one.

Availability and Compatibility:

Release 6 maps JR and JR.HB to JALR and JALR.HB with *rd* = 0:

Pre-Release 6, JR and JALR were distinct instructions, both with primary opcode SPECIAL, but with distinct function codes.

Release 6: JR is defined to be JALR with the destination register specifier *rd* set to 0. The primary opcode and function field are the same for JR and JALR. The pre-Release 6 instruction encoding is removed in Release 6.

Similarly, for JALR.HB, which continues to correspond to JALR with bit 4 of the hint field (bit 10 of the instruction) set to 1.

Release 6 assemblers should accept the JR and JR.HB mnemonics, mapping them to the Release 6 instruction encodings.

Restrictions:

This control transfer instruction has a delay slot.

JR.HB does not clear hazards created by any instruction that is executed in the delay slot of the JR.HB. Only hazards created by instructions executed before the JR.HB are cleared by the JR.HB.

After modifying an instruction stream mapping or writing to the instruction stream, execution of those instructions has **UNPREDICTABLE** behavior until the hazard has been cleared with JALR.HB, JR.HB, ERET, or DERET. Further, the operation is **UNPREDICTABLE** if the mapping of the current instruction stream is modified.

Control Transfer Instructions (CTIs) should not be in branch delay slots or forbidden slots. CTIs include all branches and jumps, NAL, ERET, ERETNC, DERET, WAIT, and PAUSE. See 4.1.3 “Jump and Branch Instructions” on page 86 in Volume I for detailed discussion of correctness and performance issues.

Pre-Release 6: Processor operation is **UNPREDICTABLE** if a control transfer instruction (CTI) is placed in the delay slot of a branch or jump.

Release 6: If a control transfer instruction (CTI) is executed in the delay slot of a branch or jump, Release 6 implementations are required to signal a Reserved Instruction Exception.

Restrictions Related to Multiple Instruction Sets: This instruction can change the active instruction set, if more than one instruction set is implemented.

If only one instruction set is implemented, then the effective target address must obey the alignment rules of the instruction set. If multiple instruction sets are implemented, the effective target address must obey the alignment rules of the intended instruction set of the target address as specified by the bit 0 or GPR *rs*.

For processors that do not implement the microMIPS ISA, the effective target address in GPR *rs* must be naturally-aligned. For processors that do not implement the MIPS16 ASE or microMIPS ISA, if either of the two least-significant bits are not zero, an Address Error exception occurs when the branch target is subsequently fetched as an instruction.

For processors that do implement the MIPS16 ASE or microMIPS ISA, if bit 0 is zero and bit 1 is one, an Address Error exception occurs when the jump target is subsequently fetched as an instruction.

Operation:

```

I: temp ← GPR[rs]
I+1: if Config1CA = 0 then
    PC ← temp
    else
        PC ← tempGPREN-1..1 || 0
        ISAMode ← temp0
    endif
    ClearHazards()

```

Exceptions:

None

Programming Notes:

This instruction implements the final step in clearing execution and instruction hazards before execution continues. A hazard is created when a Coprocessor 0 or TLB write affects execution or the mapping of the instruction stream, or after a write to the instruction stream. When such a situation exists, software must explicitly indicate to hardware that the hazard should be cleared. Execution hazards alone can be cleared with the EHB instruction. Instruction hazards can only be cleared with a JR.HB, JALR.HB, or ERET instruction. These instructions cause hardware to clear the hazard before the instruction at the target of the jump is fetched. Note that because these instructions are encoded as jumps, the process of clearing an instruction hazard can often be included as part of a call (JALR) or return (JR)

sequence, by simply replacing the original instructions with the HB equivalent.

Example: Clearing hazards due to an ASID change

```
/*
 * Routine called to modify ASID and return with the new
 * mapping established.
 *
 * a0 = New ASID to establish
 */
mfc0    v0, C0_EntryHi      /* Read current ASID */
li      v1, ~M_EntryHiASID /* Get negative mask for field */
and     v0, v0, v1          /* Clear out current ASID value */
or      v0, v0, a0          /* OR in new ASID value */
mtc0    v0, C0_EntryHi      /* Rewrite EntryHi with new ASID */
jr.hb   ra                  /* Return, clearing the hazard */
nop
```

Example: Making a write to the instruction stream visible

```
/*
 * Routine called after new instructions are written to
 * make them visible and return with the hazards cleared.
 */
{Synchronize the caches - see the SYNCI and CACHE instructions}
sync                      /* Force memory synchronization */
jr.hb   ra                /* Return, clearing the hazard */
nop
```

Example: Clearing instruction hazards in-line

```
la      AT, 10f
jr.hb   AT                /* Jump to next instruction, clearing */
nop                      /* hazards */
10:
```

Format: LB *rt*, *offset* (*base*)

MIPS32

Purpose: Load Byte

To load a byte from memory as a signed value.

Description: $GPR[rt] \leftarrow \text{memory}[GPR[base] + \text{offset}]$

The contents of the 8-bit byte at the memory location specified by the effective address are fetched, sign-extended, and placed in GPR *rt*. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

None

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
pAddr ← pAddr_PSIZE-1..2 || (pAddr_1..0 xor ReverseEndian2)
memword ← LoadMemory (CCA, BYTE, pAddr, vAddr, DATA)
byte ← vAddr_1..0 xor BigEndianCPU2
GPR[rt] ← sign_extend(memword7+8*byte..8*byte)

```

Exceptions:

TLB Refill, TLB Invalid, Address Error, Watch

Format: LBE *rt*, *offset*(*base*)

MIPS32

Purpose: Load Byte EVA

To load a byte as a signed value from user mode virtual address space when executing in kernel mode.

Description: $GPR[rt] \leftarrow \text{memory}[GPR[base] + \text{offset}]$

The contents of the 8-bit byte at the memory location specified by the effective address are fetched, sign-extended, and placed in GPR *rt*. The 9-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

The LBE instruction functions the same as the LB instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode and executing in kernel mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to one.

Restrictions:

Only usable when access to Coprocessor0 is enabled and accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
pAddr ← pAddrPSIZE-1..2 || (pAddr1..0 xor ReverseEndian2)
memword ← LoadMemory (CCA, BYTE, pAddr, vAddr, DATA)
byte ← vAddr1..0 xor BigEndianCPU2
GPR[rt] ← sign_extend(memword7+8*byte..8*byte)

```

Exceptions:

TLB Refill

TLB Invalid

Bus Error

Address Error

Watch

Reserved Instruction

Coprocessor Unusable

Format: LBU *rt*, *offset*(*base*)

MIPS32

Purpose: Load Byte Unsigned

To load a byte from memory as an unsigned value

Description: $GPR[rt] \leftarrow memory[GPR[base] + offset]$

The contents of the 8-bit byte at the memory location specified by the effective address are fetched, zero-extended, and placed in GPR *rt*. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

None

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
pAddr ← pAddr_PSIZE-1..2 || (pAddr_1..0 xor ReverseEndian2)
memword ← LoadMemory (CCA, BYTE, pAddr, vAddr, DATA)
byte ← vAddr_1..0 xor BigEndianCPU2
GPR[rt] ← zero_extend(memword7+8*byte..8*byte)

```

Exceptions:

TLB Refill, TLB Invalid, Address Error, Watch

Format: LBUE *rt*, *offset*(*base*)

MIPS32

Purpose: Load Byte Unsigned EVA

To load a byte as an unsigned value from user mode virtual address space when executing in kernel mode.

Description: $GPR[rt] \leftarrow memory[GPR[base] + offset]$

The contents of the 8-bit byte at the memory location specified by the effective address are fetched, zero-extended, and placed in GPR *rt*. The 9-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

The LBUE instruction functions the same as the LBU instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to one.

Restrictions:

Only usable when access to Coprocessor0 is enabled and accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
pAddr ← pAddrPSIZE-1..2 || (pAddr1..0 xor ReverseEndian2)
memword ← LoadMemory (CCA, BYTE, pAddr, vAddr, DATA)
byte ← vAddr1..0 xor BigEndianCPU2
GPR[rt] ← zero_extend(memword7+8*byte..8*byte)

```

Exceptions:

TLB Refill

TLB Invalid

Bus Error

Address Error

Watch

Reserved Instruction

Coprocessor Unusable

Format: LDC1 ft, offset(base)

MIPS32

Purpose: Load Doubleword to Floating Point

To load a doubleword from memory to an FPR.

Description: $\text{FPR}[\text{ft}] \leftarrow \text{memory}[\text{GPR}[\text{base}] + \text{offset}]$

The contents of the 64-bit doubleword at the memory location specified by the aligned effective address are fetched and placed in FPR *ft*. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

Pre-Release 6: An Address Error exception occurs if $\text{EffectiveAddress}_{2,0} \neq 0$ (not doubleword-aligned).

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses”](#) on page 511.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
paddr ← paddr xor ((BigEndianCPU xor ReverseEndian) || 02)
memlsw ← LoadMemory(CCA, WORD, pAddr, vAddr, DATA)
paddr ← paddr xor 0b100
memmsw ← LoadMemory(CCA, WORD, pAddr, vAddr+4, DATA)
memdoubleword ← memmsw || memlsw
StoreFPR(ft, UNINTERPRETED_DOUBLEWORD, memdoubleword)

```

Exceptions:

Coprocessor Unusable, Reserved Instruction, TLB Refill, TLB Invalid, Address Error, Watch

pre-Release 6

Release 6

**Format:** LDC2 *rt*, *offset*(*base*)**MIPS32****Purpose:** Load Doubleword to Coprocessor 2

To load a doubleword from memory to a Coprocessor 2 register.

Description: $CPR[2,rt,0] \leftarrow \text{memory}[GPR[base] + \text{offset}]$

The contents of the 64-bit doubleword at the memory location specified by the aligned effective address are fetched and placed in Coprocessor 2 register *rt*. The bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:Pre-Release 6: An Address Error exception occurs if $\text{EffectiveAddress}_{2..0} \neq 0$ (not doubleword-aligned).

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses”](#) on page 511.

Availability and Compatibility:

This instruction has been reallocated an opcode in Release 6.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, LOAD)
paddr ← paddr xor ((BigEndianCPU xor ReverseEndian) || 02)
memlsw ← LoadMemory(CCA, WORD, pAddr, vAddr, DATA)
paddr ← paddr xor 0b100
memmsw ← LoadMemory(CCA, WORD, pAddr, vAddr+4, DATA)
←memlsw
←memmsw

```

Exceptions:

Coprocessor Unusable, Reserved Instruction, TLB Refill, TLB Invalid, Address Error, Watch

Programming Notes:

As shown in the instruction drawing above, Release 6 implements an 11-bit offset, whereas all release levels lower than Release 6 of the MIPS architecture implement a 16-bit offset.

31	26	25	21	20	16	15	11	10	6	5	0

Format: LDXC1 fd, index(base)

removed in Release 6
MIPS32 Release 2, removed in Release 6

Purpose: Load Doubleword Indexed to Floating Point

To load a doubleword from memory to an FPR (GPR+GPR addressing)

Description: $\text{FPR}[\text{fd}] \leftarrow \text{memory}[\text{GPR}[\text{base}] + \text{GPR}[\text{index}]]$

The contents of the 64-bit doubleword at the memory location specified by the aligned effective address are fetched and placed in FPR *fd*. The contents of GPR *index* and GPR *base* are added to form the effective address.

Restrictions:

An Address Error exception occurs if $\text{EffectiveAddress}_{2..0} \neq 0$ (not doubleword-aligned).

Availability and Compatibility:

This instruction has been removed in Release 6.

Required in all versions of MIPS64 since MIPS64 Release 1. Not available in MIPS32 Release 1. Required in MIPS32 Release 2 and all subsequent versions of MIPS32. When required, required whenever FPU is present, whether a 32-bit or 64-bit FPU, whether in 32-bit or 64-bit FP Register Mode ($\text{FIR}_{F64}=0$ or 1, $\text{Status}_{FR}=0$ or 1).

Operation:

```

vAddr ← GPR[base] + GPR[index]
if vAddr2..0 ≠ 03 then
    SignalException(AddressError)
endif
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, LOAD)
paddr ← paddr xor ((BigEndianCPU xor ReverseEndian) || 02)
memlsw ← LoadMemory(CCA, WORD, pAddr, vAddr, DATA)
paddr ← paddr xor 0b100
memmsw ← LoadMemory(CCA, WORD, pAddr, vAddr+4, DATA)
memdoubleword ← memmsw || memlsw
StoreFPR(fd, UNINTERPRETED_DOUBLEWORD, memdoubleword)

```

Exceptions:

TLB Refill, TLB Invalid, Address Error, Reserved Instruction, Coprocessor Unusable, Watch

Format: LH *rt*, *offset*(*base*)

MIPS32

Purpose: Load Halfword

To load a halfword from memory as a signed value

Description: $GPR[rt] \leftarrow memory[GPR[base] + offset]$

The contents of the 16-bit halfword at the memory location specified by the aligned effective address are fetched, sign-extended, and placed in GPR *rt*. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

Pre-Release 6: The effective address must be naturally-aligned. If the least-significant bit of the address is non-zero, an Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses”](#) on page 511.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, LOAD)
pAddr ← pAddr_PSIZE-1..2 || (pAddr_1..0 xor (ReverseEndian || 0))
memword ← LoadMemory(CCA, HALFWORD, pAddr, vAddr, DATA)
byte ← vAddr_1..0 xor (BigEndianCPU || 0)
GPR[rt] ← sign_extend(memword_15+8*byte..8*byte)

```

Exceptions:

TLB Refill, TLB Invalid, Bus Error, Address Error, Watch

Format: LHE *rt*, *offset*(*base*)

MIPS32

Purpose: Load Halfword EVA

To load a halfword as a signed value from user mode virtual address space when executing in kernel mode.

Description: $GPR[rt] \leftarrow memory[GPR[base] + offset]$

The contents of the 16-bit halfword at the memory location specified by the aligned effective address are fetched, sign-extended, and placed in GPR *rt*. The 9-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

The LHE instruction functions the same as the LH instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to one.

Restrictions:

Only usable when access to Coprocessor0 is enabled and accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

Pre-Release 6: The effective address must be naturally-aligned. If the least-significant bit of the address is non-zero, an Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses”](#) on page 511.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, LOAD)
pAddr ← pAddr_PSIZE-1..2 || (pAddr_1..0 xor (ReverseEndian || 0))
memword ← LoadMemory(CCA, HALFWORD, pAddr, vAddr, DATA)
byte ← vAddr_1..0 xor (BigEndianCPU || 0)
GPR[rt] ← sign_extend(memword_15+8*byte..8*byte)

```

pre-Release 6

Release 6

**Format:** LL *rt*, *offset*(*base*)**MIPS32****Purpose:** Load Linked Word

To load a word from memory for an atomic read-modify-write

Description: $\text{GPR}[\text{rt}] \leftarrow \text{memory}[\text{GPR}[\text{base}] + \text{offset}]$

The LL and SC instructions provide the primitives to implement atomic read-modify-write (RMW) operations for synchronizable memory locations.

The contents of the 32-bit word at the memory location specified by the aligned effective address are fetched and written into GPR *rt*. The bit signed *offset* is added to the contents of GPR *base* to form an effective address.

This begins a RMW sequence on the current processor. There can be only one active RMW sequence per processor. When an LL is executed it starts an active RMW sequence replacing any other sequence that was active. The RMW sequence is completed by a subsequent SC instruction that either completes the RMW sequence atomically and succeeds, or does not and fails.

Executing LL on one processor does not cause an action that, by itself, causes an SC for the same block to fail on another processor.

An execution of LL does not have to be followed by execution of SC; a program is free to abandon the RMW sequence without attempting a write.

Restrictions:

The addressed location must be synchronizable by all processors and I/O devices sharing the location; if it is not, the result is **UNPREDICTABLE**. Which storage is synchronizable is a function of both CPU and system implementations. See the documentation of the SC instruction for the formal definition.

The effective address must be naturally-aligned. If either of the 2 least-significant bits of the effective address is non-zero, an Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions such as LW (Load Word). However, this instruction is a special memory reference instruction for which misaligned support is NOT provided, and for which signalling an exception (AddressError) on a misaligned access is required.

Availability and Compatibility:

This instruction has been reallocated an opcode in Release 6.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
if vAddr1..0 ≠ 02 then

```

```
        SignalException(AddressError)
    endif
    (pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
    memword ← LoadMemory (CCA, WORD, pAddr, vAddr, DATA)
    GPR[rt] ← memword
    LLbit ← 1
```

Exceptions:

TLB Refill, TLB Invalid, Address Error, Watch

Programming Notes:

As shown in the instruction drawing above, Release 6 implements a 9-bit offset, whereas all release levels lower than Release 6 of the MIPS architecture implement a 16-bit offset.

Format: LLE *rt*, *offset*(*base*)

MIPS32

Purpose: Load Linked Word EVA

To load a word from a user mode virtual address when executing in kernel mode for an atomic read-modify-write

Description: $\text{GPR}[\text{rt}] \leftarrow \text{memory}[\text{GPR}[\text{base}] + \text{offset}]$

The LLE and SCE instructions provide the primitives to implement atomic read-modify-write (RMW) operations for synchronizable memory locations using user mode virtual addresses while executing in kernel mode.

The contents of the 32-bit word at the memory location specified by the aligned effective address are fetched and written into GPR *rt*. The 9-bit signed *offset* is added to the contents of GPR *base* to form an effective address.

This begins a RMW sequence on the current processor. There can be only one active RMW sequence per processor. When an LLE is executed it starts an active RMW sequence replacing any other sequence that was active. The RMW sequence is completed by a subsequent SCE instruction that either completes the RMW sequence atomically and succeeds, or does not and fails.

Executing LLE on one processor does not cause an action that, by itself, causes an SCE for the same block to fail on another processor.

An execution of LLE does not have to be followed by execution of SCE; a program is free to abandon the RMW sequence without attempting a write.

The LLE instruction functions the same as the LL instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Segmentation Control for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to one.

Restrictions:

The addressed location must be synchronizable by all processors and I/O devices sharing the location; if it is not, the result is **UNPREDICTABLE**. Which storage is synchronizable is a function of both CPU and system implementations. See the documentation of the **SCE** instruction for the formal definition.

Pre-Release 6: The effective address must be naturally-aligned. If either of the 2 least-significant bits of the effective address is non-zero, an Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions such as LW (Load Word). However, this instruction is a special memory reference instruction for which misaligned support is NOT provided, and for which signalling an exception (AddressError) on a misaligned access is required.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
if vAddr1..0 ≠ 02 then
    SignalException(AddressError)
endif
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)

```

```
memword ← LoadMemory (CCA, WORD, pAddr, vAddr, DATA)
←GPR[rt] ← memword
LLbit ← 1
```

Exceptions:

TLB Refill, TLB Invalid, Address Error, Reserved Instruction, Watch, Coprocessor Unusable

Programming Notes:

Format: LSA
LSA rd,rs,rt,sa

MIPS32 Release 6

Purpose: Load Scaled Address

Description:

LSA: $\text{GPR}[\text{rd}] \leftarrow \text{sign_extend.32}(\text{GPR}[\text{rs}] \ll (\text{sa}+1) + \text{GPR}[\text{rt}])$

LSA adds two values derived from registers *rs* and *rt*, with an optional scaling shift on *rs*. The scaling shift is formed by adding 1 to the 2-bit *sa* field, which is interpreted as unsigned. The scaling left shift varies from 1 to 5, corresponding to multiplicative scaling values of $\times 2$, $\times 4$, $\times 8$, $\times 16$, bytes, or 16, 32, 64, or 128 bits.

LSA is a MIPS32 compatible instruction, sign extending its result from bit 31 to bit 63.

Restrictions:

None

Availability and Compatibility:

LSA instruction is introduced by and required as of Release 6.

Operation

LSA: $\text{GPR}[\text{rd}] \leftarrow \text{sign_extend.32}(\text{GPR}[\text{rs}] \ll (\text{sa}+1) + \text{GPR}[\text{rt}])$

Exceptions:

None

Format: LUI *rt*, *immediate*

MIPS32, Assembly Idiom Release 6

Purpose: Load Upper Immediate

To load a constant into the upper half of a word

Description: $\text{GPR}[\text{rt}] \leftarrow \text{immediate} \parallel 0^{16}$

The 16-bit *immediate* is shifted left 16 bits and concatenated with 16 bits of low-order zeros. The 32-bit result is placed into GPR *rt*.

Restrictions:

None

Operation:

$\text{GPR}[\text{rt}] \leftarrow \text{immediate} \parallel 0^{16}$

Exceptions:

None

Programming Notes:

In Release 6, LUI is an assembly idiom of AUI with *rs*=0.

31	26	25	21	20	16	15	11	10	6	5	0				
COP1X 010011						base		index		0 00000		fd		LUXC1 000101	
6						5		5		5		5		6	

Format: LUXC1 fd, index(base)

MIPS64, removed in Release 6
MIPS32 Release 2, removed in Release 6

Purpose: Load Doubleword Indexed Unaligned to Floating Point

To load a doubleword from memory to an FPR (GPR+GPR addressing), ignoring alignment

Description: $\text{FPR}[\text{fd}] \leftarrow \text{memory}[(\text{GPR}[\text{base}] + \text{GPR}[\text{index}])_{\text{PSIZE}-1..3}]$

The contents of the 64-bit doubleword at the memory location specified by the effective address are fetched and placed into the low word of FPR *fd*. The contents of GPR *index* and GPR *base* are added to form the effective address. The effective address is doubleword-aligned; EffectiveAddress_{2..0} are ignored.

Restrictions:

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```

vAddr ← (GPR[base]+GPR[index])63..3 || 03
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, LOAD)
paddr ← paddr xor ((BigEndianCPU xor ReverseEndian) || 02)
memlsw ← LoadMemory(CCA, WORD, pAddr, vAddr, DATA)
paddr ← paddr xor 0b100
memmsw ← LoadMemory(CCA, WORD, pAddr, vAddr+4, DATA)
memdoubleword ← memmsw || memlsw
StoreFPR(ft, UNINTERPRETED_DOUBLEWORD, memdoubleword)

```

Exceptions:

Coprocessor Unusable, Reserved Instruction, TLB Refill, TLB Invalid, Watch

Format: LW *rt*, *offset* (*base*)

MIPS32

Purpose: Load Word

To load a word from memory as a signed value

Description: $GPR[rt] \leftarrow \text{memory}[GPR[base] + \text{offset}]$

The contents of the 32-bit word at the memory location specified by the aligned effective address are fetched, sign-extended to the GPR register length if necessary, and placed in GPR *rt*. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

Pre-Release 6: The effective address must be naturally-aligned. If either of the 2 least-significant bits of the address is non-zero, an Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses”](#) on page 511.

Operation:

```
vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
memword ← LoadMemory (CCA, WORD, pAddr, vAddr, DATA)
GPR[rt] ← memword
```

Exceptions:

TLB Refill, TLB Invalid, Bus Error, Address Error, Watch

Format: LWC1 ft, offset(base)

MIPS32

Purpose: Load Word to Floating Point

To load a word from memory to an FPR

Description: $\text{FPR}[ft] \leftarrow \text{memory}[\text{GPR}[base] + \text{offset}]$

The contents of the 32-bit word at the memory location specified by the aligned effective address are fetched and placed into the low word of FPR *ft*. If FPRs are 64 bits wide, bits 63..32 of FPR *ft* become **UNPREDICTABLE**. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

Pre-Release 6: An Address Error exception occurs if $\text{EffectiveAddress}_{1..0} \neq 0$ (not word-aligned).

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses” on page 511](#).

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)

memword ← LoadMemory(CCA, WORD, pAddr, vAddr, DATA)

StoreFPR(ft, UNINTERPRETED_WORD,
          memword)

```

Exceptions:

TLB Refill, TLB Invalid, Address Error, Reserved Instruction, Coprocessor Unusable, Watch

pre-Release 6

Release 6

**Format:** LWC2 *rt*, *offset*(*base*)**MIPS32****Purpose:** Load Word to Coprocessor 2

To load a word from memory to a COP2 register.

Description: $CPR[2,rt,0] \leftarrow \text{memory}[GPR[base] + offset]$

The contents of the 32-bit word at the memory location specified by the aligned effective address are fetched and placed into the low word of *COP2* (Coprocessor 2) general register *rt*. The signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:Pre-Release 6: An Address Error exception occurs if $\text{EffectiveAddress}_{1..0} \neq 0$ (not word-aligned).

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses” on page 511](#).

Availability and Compatibility:

This instruction has been reallocated an opcode in Release 6.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
if vAddr12..0 ≠ 02 then
  (pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)

memword ← LoadMemory(CCA, DOUBLEWORD, pAddr, vAddr, DATA)

CPR[2,rt,0] ← memword

```

Exceptions:

TLB Refill, TLB Invalid, Address Error, Reserved Instruction, Coprocessor Unusable, Watch

Programming Notes:

As shown in the instruction drawing above, Release 6 implements an 11-bit offset, whereas all release levels lower

than Release 6 of the MIPS architecture implement a 16-bit offset.

Format: LWE *rt*, *offset*(*base*)

MIPS32

Purpose: Load Word EVA

To load a word from user mode virtual address space when executing in kernel mode.

Description: $GPR[rt] \leftarrow memory[GPR[base] + offset]$

The contents of the 32-bit word at the memory location specified by the aligned effective address are fetched, sign-extended to the GPR register length if necessary, and placed in GPR *rt*. The 9-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

The LWE instruction functions the same as the LW instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to one.

Restrictions:

Only usable when access to Coprocessor0 is enabled and when accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

Pre-Release 6: The effective address must be naturally-aligned. If either of the 2 least-significant bits of the address is non-zero, an Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses” on page 511](#).

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
memword ← LoadMemory (CCA, WORD, pAddr, vAddr, DATA)
GPR[rt] ← memword

```

Exceptions:

Reserved Instruction

Coprocessor Unusable

Format: LWL *rt*, *offset*(*base*)

MIPS32, removed in Release 6

Purpose: Load Word Left

To load the most-significant part of a word as a signed value from an unaligned memory address

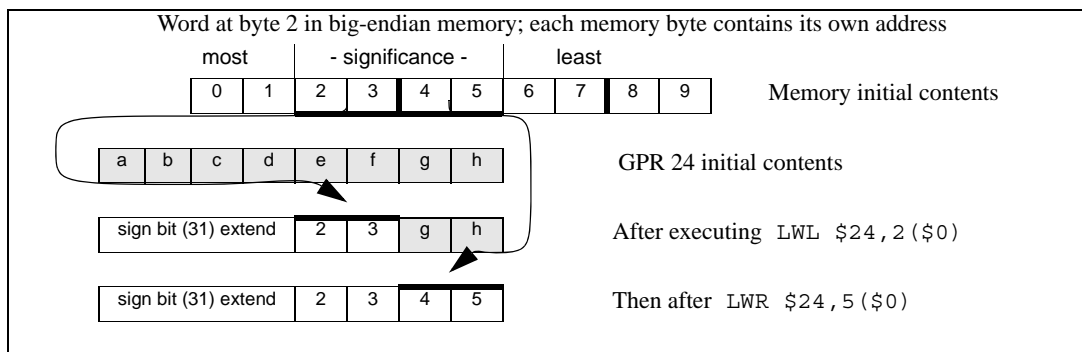

Description: $GPR[rt] \leftarrow GPR[rt] \text{ MERGE } \text{memory}[GPR[base] + \text{offset}]$

The 16-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the most-significant of 4 consecutive bytes forming a word (*W*) in memory starting at an arbitrary byte boundary.

The most-significant 1 to 4 bytes of *W* is in the aligned word containing the *EffAddr*. This part of *W* is loaded into the most-significant (left) part of the word in GPR *rt*. The remaining least-significant part of the word in GPR *rt* is unchanged.

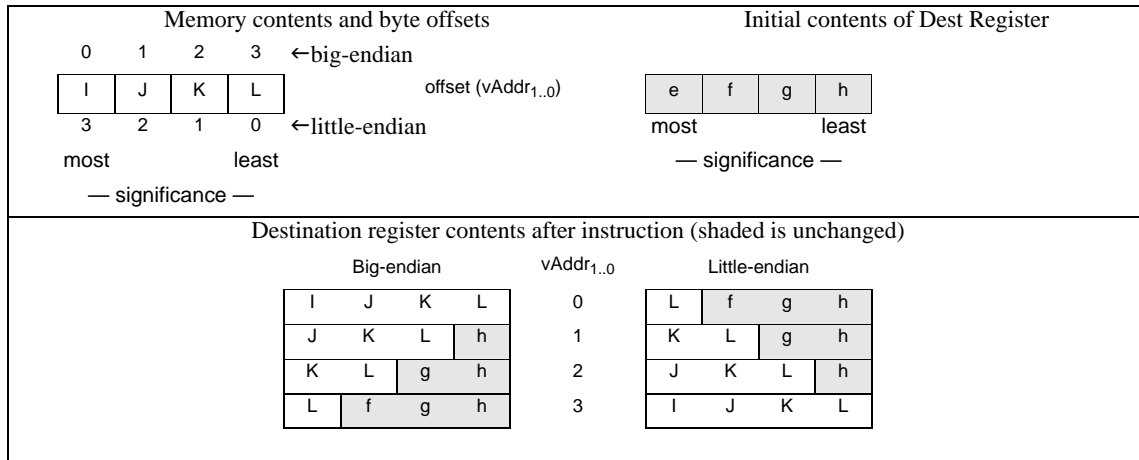

The figure below illustrates this operation using big-endian byte ordering for 32-bit and 64-bit registers. The 4 consecutive bytes in 2..5 form an unaligned word starting at location 2. A part of *W*, 2 bytes, is in the aligned word containing the most-significant byte at 2. First, LWL loads these 2 bytes into the left part of the destination register word and leaves the right part of the destination word unchanged. Next, the complementary LWR loads the remainder of the unaligned word

Figure 4.1 Unaligned Word Load Using LWL and LWR

The bytes loaded from memory to the destination register depend on both the offset of the effective address within an aligned word, that is, the low 2 bits of the address ($vAddr_{1..0}$), and the current byte-ordering mode of the processor (big- or little-endian). The figure below shows the bytes loaded for every combination of offset and byte ordering.

Figure 4.2 Bytes Loaded by LWL Instruction

**Restrictions:**

None

Availability and Compatibility:

Release 6 removes the load/store-left/right family of instructions, and requires the system to support misaligned memory accesses.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
pAddr ← pAddrPSIZE-1..2 || (pAddr1..0 xor ReverseEndian2)
if BigEndianMem = 0 then
    pAddr ← pAddrPSIZE-1..2 || 02
endif
byte ← vAddr1..0 xor BigEndianCPU2
memword ← LoadMemory (CCA, byte, pAddr, vAddr, DATA)
temp ← memword7+8*byte..0 || GPR[rt]23-8*byte..0
GPR[rt] ← temp

```

Exceptions:

None

TLB Refill, TLB Invalid, Bus Error, Address Error, Watch

Programming Notes:

The architecture provides no direct support for treating unaligned words as unsigned values, that is, zeroing bits 63..32 of the destination register when bit 31 is loaded.

Historical Information:

In the MIPS I architecture, the LWL and LWR instructions were exceptions to the load-delay scheduling restriction. A LWL or LWR instruction which was immediately followed by another LWL or LWR instruction, and used the same destination register would correctly merge the 1 to 4 loaded bytes with the data loaded by the previous instruction. All such restrictions were removed from the architecture in MIPS II.

Format: LWLE *rt*, *offset*(*base*)

MIPS32, removed in Release 6

Purpose: Load Word Left EVA

To load the most-significant part of a word as a signed value from an unaligned user mode virtual address while executing in kernel mode.

Description: $GPR[rt] \leftarrow GPR[rt] \text{ MERGE } \text{memory}[GPR[base] + \text{offset}]$

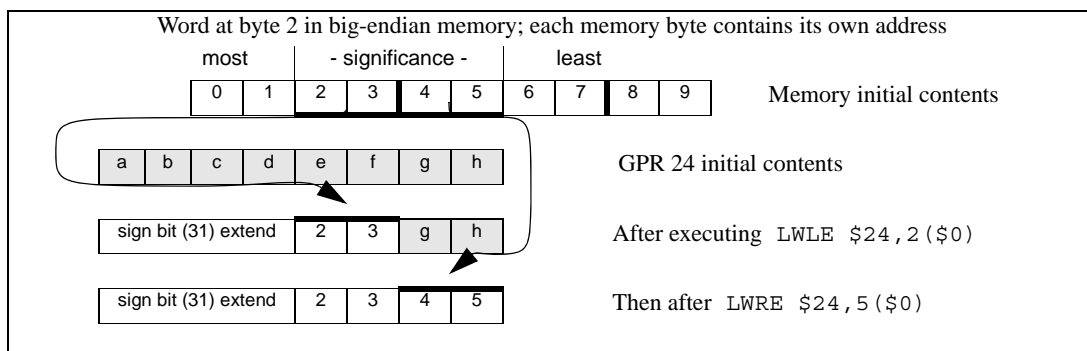

The 9-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the most-significant of 4 consecutive bytes forming a word (*W*) in memory starting at an arbitrary byte boundary.

The most-significant 1 to 4 bytes of *W* is in the aligned word containing the *EffAddr*. This part of *W* is loaded into the most-significant (left) part of the word in GPR *rt*. The remaining least-significant part of the word in GPR *rt* is unchanged.

The figure below illustrates this operation using big-endian byte ordering for 32-bit and 64-bit registers. The 4 consecutive bytes in 2..5 form an unaligned word starting at location 2. A part of *W* (2 bytes) is in the aligned word containing the most-significant byte at 2.

1. LWLE loads these 2 bytes into the left part of the destination register word and leaves the right part of the destination word unchanged.
2. The complementary LWRE loads the remainder of the unaligned word.

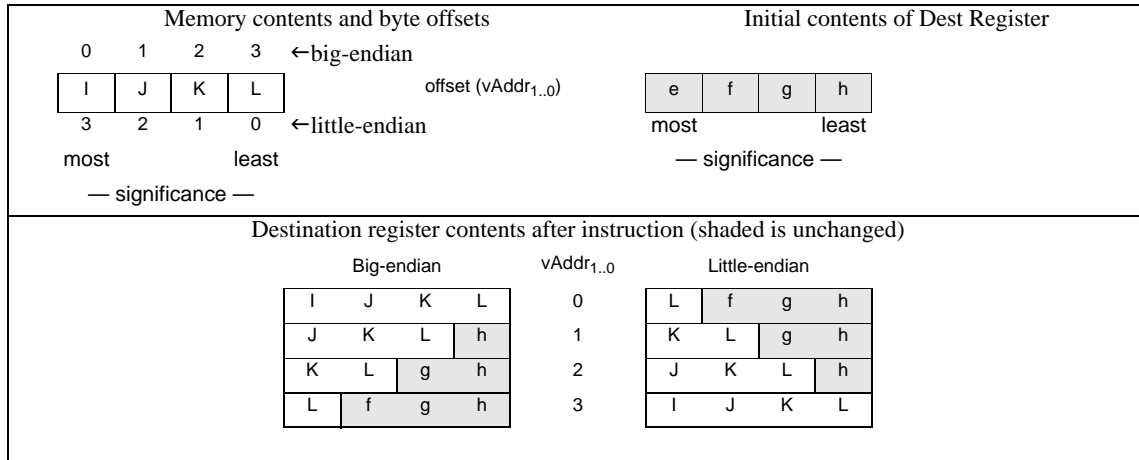

Figure 4.3 Unaligned Word Load Using LWLE and LWRE

The bytes loaded from memory to the destination register depend on both the offset of the effective address within an aligned word, that is, the low 2 bits of the address ($vAddr_{1,0}$), and the current byte-ordering mode of the processor (big- or little-endian). The figure below shows the bytes loaded for every combination of offset and byte ordering.

The LWLE instruction functions the same as the LWL instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to 1.

Figure 4.4 Bytes Loaded by LWLE Instruction**Restrictions:**

Only usable when access to Coprocessor0 is enabled and when accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

Availability and Compatibility:

Release 6 removes the load/store-left/right family of instructions, and requires the system to support misaligned memory accesses.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, LOAD)
pAddr ← pAddrPSIZE-1..2 || (pAddr1..0 xor ReverseEndian2)
if BigEndianMem = 0 then
    pAddr ← pAddrPSIZE-1..2 || 02
endif
byte ← vAddr1..0 xor BigEndianCPU2
memword ← LoadMemory(CCA, byte, pAddr, vAddr, DATA)
temp ← memword7+8*byte..0 || GPR[rt]23-8*byte..0
GPR[rt] ← temp

```

Exceptions:

TLB Refill, TLB Invalid, Bus Error, Address Error, Watch, Reserved Instruction, Coprocessor Unusable

Programming Notes:

The architecture provides no direct support for treating unaligned words as unsigned values, that is, zeroing bits 63..32 of the destination register when bit 31 is loaded.

Historical Information:

In the MIPS I architecture, the LWL and LWR instructions were exceptions to the load-delay scheduling restriction. A LWL or LWR instruction which was immediately followed by another LWL or LWR instruction, and used the

same destination register would correctly merge the 1 to 4 loaded bytes with the data loaded by the previous instruction. All such restrictions were removed from the architecture in MIPS II.

Format: LWPC rs, offset

MIPS32 Release 6

Purpose: Load Word PC-relative

To load a word from memory as a signed value, using a PC-relative address.

Description: $GPR[rs] \leftarrow \text{memory}[PC + \text{sign_extend}(\text{offset} \ll 2)]$

The offset is shifted left by 2 bits, sign-extended, and added to the address of the LWPC instruction.

The contents of the 32-bit word at the memory location specified by the aligned effective address are fetched, sign-extended to the GPR register length if necessary, and placed in GPR *rt*.

Restrictions:

None.

LWPC is naturally aligned, by specification.

Availability and Compatibility:

This instruction is introduced by and required as of Release 6.

Operation

```

vAddr ← ( PC + sign_extend(offset) << 2 )
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
memword ← LoadMemory (CCA, WORD, pAddr, vAddr, DATA)
GPR[rt] ← memword

```

Exceptions:

TLB Refill, TLB Invalid, TLB Read Inhibit, Bus Error, Address Error, Watch

Programming Note

The Release 6 PC-relative loads (LWPC) are considered data references.

For the purposes of watchpoints (provided by the CP0 *WatchHi* and *WatchLo* registers) and EJTAG breakpoints, the PC-relative reference is considered to be a data reference rather than an instruction reference. That is, the watchpoint or breakpoint is triggered only if enabled for data references.

Format: LWR *rt*, *offset*(*base*)

MIPS32, removed in Release 6

Purpose: Load Word Right

To load the least-significant part of a word from an unaligned memory address as a signed value

Description: $GPR[rt] \leftarrow GPR[rt] \text{ MERGE } \text{memory}[GPR[base] + \text{offset}]$

The 16-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the least-significant of 4 consecutive bytes forming a word (*W*) in memory starting at an arbitrary byte boundary.

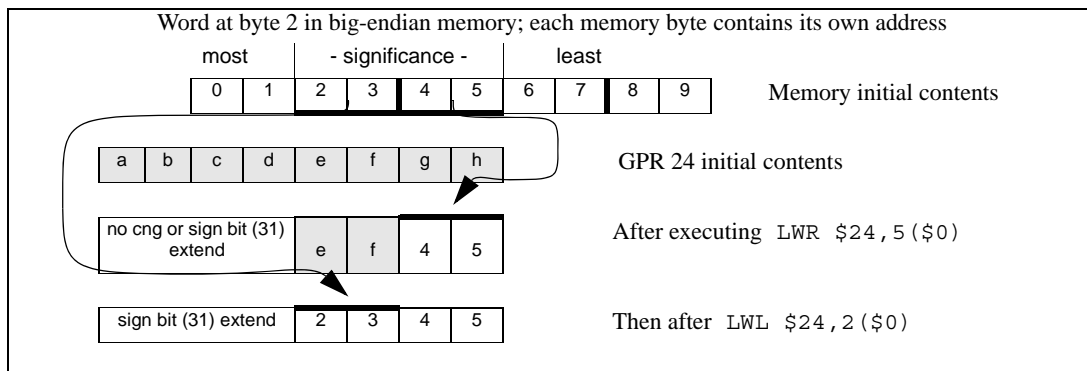

A part of *W* (the least-significant 1 to 4 bytes) is in the aligned word containing *EffAddr*. This part of *W* is loaded into the least-significant (right) part of the word in GPR *rt*. The remaining most-significant part of the word in GPR *rt* is unchanged.

Executing both LWR and LWL, in either order, delivers a sign-extended word value in the destination register.

The figure below illustrates this operation using big-endian byte ordering for 32-bit and 64-bit registers. The 4 consecutive bytes in 2..5 form an unaligned word starting at location 2. A part of *W*, 2 bytes, is in the aligned word containing the least-significant byte at 5.

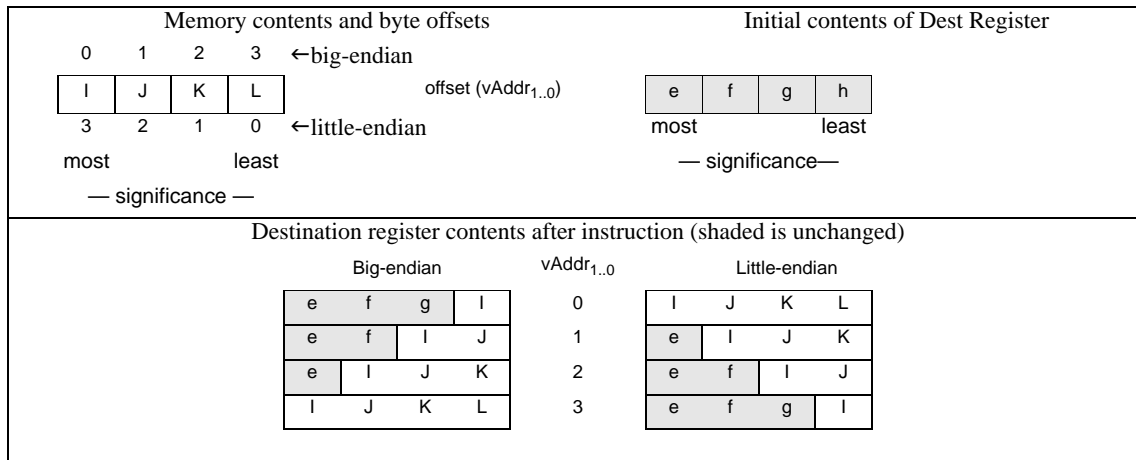

1. LWR loads these 2 bytes into the right part of the destination register.
2. The complementary LWL loads the remainder of the unaligned word.

Figure 4.5 Unaligned Word Load Using LWL and LWR

The bytes loaded from memory to the destination register depend on both the offset of the effective address within an aligned word, that is, the low 2 bits of the address ($vAddr_{1..0}$), and the current byte-ordering mode of the processor (big- or little-endian). The figure below shows the bytes loaded for every combination of offset and byte ordering.

Figure 4.6 Bytes Loaded by LWR Instruction

**Restrictions:**

None

Availability and Compatibility:

Release 6 removes the load/store-left/right family of instructions, and requires the system to support misaligned memory accesses.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
pAddr ← pAddrPSIZE-1..2 || (pAddr1..0 xor ReverseEndian2)
if BigEndianMem = 0 then
    pAddr ← pAddrPSIZE-1..2 || 02
endif
byte ← vAddr1..0 xor BigEndianCPU2
memword ← LoadMemory (CCA, byte, pAddr, vAddr, DATA)
temp ← memword31..32-8*byte || GPR[rt]31-8*byte..0
GPR[rt] ← temp

```

Exceptions:

TLB Refill, TLB Invalid, Bus Error, Address Error, Watch

Programming Notes:

The architecture provides no direct support for treating unaligned words as unsigned values, that is, zeroing bits 63..32 of the destination register when bit 31 is loaded.

Historical Information:

In the MIPS I architecture, the LWL and LWR instructions were exceptions to the load-delay scheduling restriction. A LWL or LWR instruction which was immediately followed by another LWL or LWR instruction, and used the same destination register would correctly merge the 1 to 4 loaded bytes with the data loaded by the previous instruction. All such restrictions were removed from the architecture in MIPS II.

Format: LWRE *rt*, offset(*base*)

MIPS32, removed in Release 6

Purpose: Load Word Right EVA

To load the least-significant part of a word from an unaligned user mode virtual memory address as a signed value while executing in kernel mode.

Description: $GPR[rt] \leftarrow GPR[rt] \text{ MERGE } \text{memory}[GPR[base] + \text{offset}]$

The 9-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the least-significant of 4 consecutive bytes forming a word (*W*) in memory starting at an arbitrary byte boundary.

A part of *W* (the least-significant 1 to 4 bytes) is in the aligned word containing *EffAddr*. This part of *W* is loaded into the least-significant (right) part of the word in GPR *rt*. The remaining most-significant part of the word in GPR *rt* is unchanged.

Executing both LWRE and LWLE, in either order, delivers a sign-extended word value in the destination register.

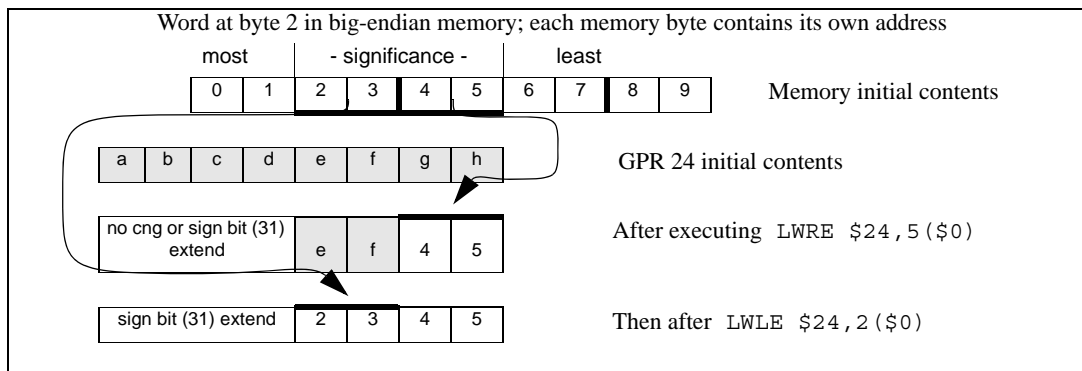

The figure below illustrates this operation using big-endian byte ordering for 32-bit and 64-bit registers. The 4 consecutive bytes in 2..5 form an unaligned word starting at location 2. A part of *W* (2 bytes) is in the aligned word containing the least-significant byte at 5.

1. LWRE loads these 2 bytes into the right part of the destination register.
2. The complementary LWLE loads the remainder of the unaligned word.

The LWRE instruction functions in exactly the same fashion as the LWR instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

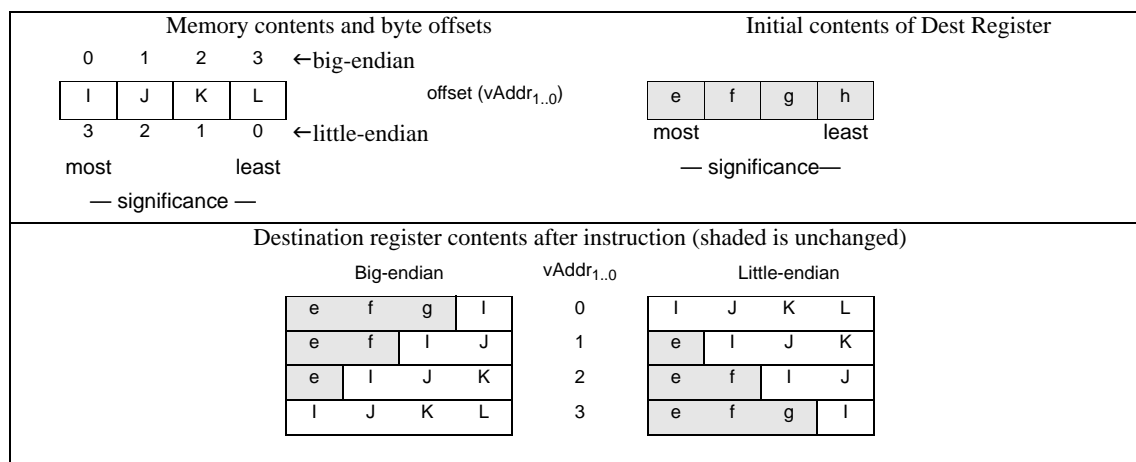

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to one.

Figure 4.7 Unaligned Word Load Using LWLE and LWRE

The bytes loaded from memory to the destination register depend on both the offset of the effective address within an aligned word, that is, the low 2 bits of the address ($vAddr_{1..0}$), and the current byte-ordering mode of the processor (big- or little-endian). The figure below shows the bytes loaded for every combination of offset and byte ordering.

Figure 4.8 Bytes Loaded by LWRE Instruction

Restrictions:

Only usable when access to Coprocessor0 is enabled and when accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

Availability and Compatibility:

Release 6 removes the load/store-left/right family of instructions, and requires the system to support misaligned memory accesses.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
pAddr ← pAddr_PSIZE-1..2 || (pAddr_1..0 xor ReverseEndian2)
if BigEndianMem = 0 then
    pAddr ← pAddr_PSIZE-1..2 || 02
    
```

```
endif
byte ← vAddr1..0 xor BigEndianCPU2
memword ← LoadMemory (CCA, byte, pAddr, vAddr, DATA)
temp ← memword31..32-8*byte || GPR[rt]31-8*byte..0
GPR[rt] ← temp
```

Exceptions:

TLB Refill, TLB Invalid, Bus Error, Address Error, Watch, Reserved Instruction, Coprocessor Unusable

Programming Notes:

The architecture provides no direct support for treating unaligned words as unsigned values, that is, zeroing bits 63..32 of the destination register when bit 31 is loaded.

Historical Information:

In the MIPS I architecture, the LWL and LWR instructions were exceptions to the load-delay scheduling restriction. A LWL or LWR instruction which was immediately followed by another LWL or LWR instruction, and used the same destination register would correctly merge the 1 to 4 loaded bytes with the data loaded by the previous instruction. All such restrictions were removed from the architecture in MIPS II.

Format: LWXC1 *fd*, *index*(*base*)

removed in Release 6
MIPS32 Release 2, removed in Release 6

Purpose: Load Word Indexed to Floating Point

To load a word from memory to an FPR (GPR+GPR addressing).

Description: $\text{FPR}[\text{fd}] \leftarrow \text{memory}[\text{GPR}[\text{base}] + \text{GPR}[\text{index}]]$

The contents of the 32-bit word at the memory location specified by the aligned effective address are fetched and placed into the low word of FPR *fd*. If FPRs are 64 bits wide, bits 63..32 of FPR *fs* become **UNPREDICTABLE**. The contents of GPR *index* and GPR *base* are added to form the effective address.

Restrictions:

An Address Error exception occurs if $\text{EffectiveAddress}_{1..0} \neq 0$ (not word-aligned).

Availability and Compatibility:

This instruction has been removed in Release 6.

Required in all versions of MIPS64 since MIPS64 Release 1. Not available in MIPS32 Release 1. Required in MIPS32 Release 2 and all subsequent versions of MIPS32. When required, required whenever FPU is present, whether a 32-bit or 64-bit FPU, whether in 32-bit or 64-bit FP Register Mode ($\text{FIR}_{F64}=0$ or 1, $\text{Status}_{FR}=0$ or 1).

Operation:

```

vAddr ← GPR[base] + GPR[index]
if vAddr1..0 ≠ 02 then
    SignalException(AddressError)
endif
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)

memword ← LoadMemory(CCA, WORD, pAddr, vAddr, DATA)

StoreFPR(fd, UNINTERPRETED_WORD,
          memword)

```

Exceptions:

SPECIAL2 011100			rs		rt		0 0000		0 00000		MADD 000000
6			5		5		5		5		6

Format: MADD rs, rt

MIPS32, removed in Release 6

Purpose: Multiply and Add Word to Hi, Lo

To multiply two words and add the result to Hi, Lo.

Description: $(HI, LO) \leftarrow (HI, LO) + (GPR[rs] \times GPR[rt])$

The 32-bit word value in GPR *rs* is multiplied by the 32-bit word value in GPR *rt*, treating both operands as signed values, to produce a 64-bit result. The product is added to the 64-bit concatenated values of *HI* and *LO*. The most significant 32 bits of the result are written into *HI* and the least significant 32 bits are written into *LO*. No arithmetic exception occurs under any circumstances.

Restrictions:

This instruction does not provide the capability of writing directly to a target GPR.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```
temp ← (HI || LO) + (GPR[rs] × GPR[rt])
HI ← temp63..32
LO ← temp31..0
```

Exceptions:

None

Programming Notes:

Where the size of the operands are known, software should place the shorter operand in GPR *rt*. This may reduce the latency of the instruction on those processors which implement data-dependent instruction latencies.

31	26	25	21	20	16	15	11	10	6	5	3	2	0				
COP1X 010011						fr		ft		fs		fd		MADD 100	fmt		
6						5		5		5		5		3		3	

Format: MADD.fmt
MADD.S fd, fr, fs, ft
MADD.D fd, fr, fs, ft
MADD.PS fd, fr, fs, ft

MIPS32 Release 2, removed in Release 6
MIPS32 Release 2, removed in Release 6
MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Multiply Add

To perform a combined multiply-then-add of FP values.

Description: $FPR[fd] \leftarrow (FPR[fs] \times FPR[ft]) + FPR[fr]$

The value in FPR *fs* is multiplied by the value in FPR *ft* to produce an intermediate product.

The intermediate product is rounded according to the current rounding mode in *FCSR*. The value in FPR *fr* is added to the product. The result sum is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operands and result are values in format *fmt*. The results and flags are as if separate floating-point multiply and add instructions were executed.

MADD.PS multiplies then adds the upper and lower halves of FPR *fr*, FPR *fs*, and FPR *ft* independently, and ORs together any generated exceptional conditions.

The *Cause* bits are ORed into the *Flag* bits if no exception is taken.

Restrictions:

The fields *fr*, *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of MADD.PS is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

MADD.S and MADD.D: Required in all versions of MIPS64 since MIPS64 Release 1. Not available in MIPS32 Release 1. Required in MIPS32 Release 2 and all subsequent versions of MIPS32. When required, these instructions are to be implemented if an FPU is present either in a 32-bit or 64-bit FPU or in a 32-bit or 64-bit FP Register Mode (*FIR*_{F64}=0 or 1, *Status*_{FR}=0 or 1).

This instruction has been removed in Release 6 and has been replaced by the fused multiply-add instruction. Refer to the fused multiply-add instruction ‘MADDF.fmt’ in this manual for more information. Release 6 does not support Paired Single (PS).

Operation:

```
vfr ← ValueFPR(fr, fmt)
vfs ← ValueFPR(fs, fmt)
vft ← ValueFPR(ft, fmt)
StoreFPR(fd, fmt, (vfs ×fmt vft) +fmt vfr)
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Unimplemented Operation, Invalid Operation, Overflow, Underflow

31	26	25	21	20	16	15	11	10	6	5	0

6	5					5					3

Format: MADDF.fmt MSUBF.fmt
MADDF.S fd, fs, ft
MADDF.D fd, fs, ft
MSUBF.S fd, fs, ft
MSUBF.D fd, fs, ft

MIPS32 Release 6
MIPS32 Release 6
MIPS32 Release 6
MIPS32 Release 6

Purpose: Floating Point Fused Multiply Add, Floating Point Fused Multiply Subtract

MADDF.fmt: To perform a fused multiply-add of FP values.

MSUBF.fmt: To perform a fused multiply-subtract of FP values.

Description:

MADDF.fmt: $FPR[fd] \leftarrow FPR[fd] + (FPR[fs] \times FPR[ft])$

MSUBF.fmt: $FPR[fd] \leftarrow FPR[fd] - (FPR[fs] \times FPR[ft])$

The value in $FPR[fs]$ is multiplied by the value in $FPR[ft]$ to produce an intermediate product. The intermediate product is calculated to infinite precision. The product is added to the value in $FPR[fd]$. The result sum is calculated to infinite precision, rounded according to the current rounding mode in $FCSR$, and placed into $FPR[fd]$. The operands and result are values in format *fmt*.

(For MSUBF.fmt, the product is subtracted from the value in $FPR[fd]$.)

Cause bits are ORed into the *Flag* bits if no exception is taken.

Restrictions:

None

Availability and Compatibility:

MADDF.fmt and MSUBF.fmt are required in Release 6.

MADDF.fmt and MSUBF.fmt are not available in architectures pre-Release 6.

The fused multiply add instructions, MADDF.fmt and MSUBF.fmt, replace pre-Release 6 instructions such as MADD.fmt, MSUB.fmt, NMADD.fmt, and NMSUB.fmt. The replaced instructions were unfused multiply-add, with an intermediate rounding, although in some earlier implementations they were fused. Instructions such as MADD.fmt were usually unfused, but were occasionally fused. Release 6 provides consistent behavior: MADDF.fmt and MSUBF.fmt are required to be fused in all implementations.

Release 6 MSUBF.fmt, $fd \leftarrow fd - fs \times ft$, corresponds more closely to pre-Release 6 NMADD.fmt, $fd \leftarrow fr - fs \times ft$, than to pre-Release 6 MSUB.fmt, $fd \leftarrow fs \times ft - fr$.

FPU scalar MADDF.fmt corresponds to MSA vector MADD.df.

FPU scalar MSUBF.fmt corresponds to MSA vector MSUB.df.

Operation:

```

if not IsCoproprocessorEnabled(1)
    then SignalException(CoproprocessorUnusable, 1) end if
if not IsFloatingPointImplemented(fmt)
    then SignalException(ReservedInstruction) end if
if fmt=D and FIR.D=0
    then SignalFPEException(UnimplementedOperation) end if

vfr ← ValueFPR(fr, fmt)
vfs ← ValueFPR(fs, fmt)
vfd ← ValueFPR(fd, fmt)
MADDF.fmt: vinf ← vfd +∞ (vfs *∞ vft)
MADDF.fmt: vinf ← vfd -∞ (vfs *∞ vft)
StoreFPR(fd, fmt, vinf)

```

Special Considerations:

The fused multiply-add computation is performed in infinite precision, and signals Inexact, Overflow, or Underflow if and only if the final result differs from the infinite precision result in the appropriate manner.

Like most FPU computational instructions, if the flush-subnormals-to-zero mode, FCSR.FS=1, then subnormals are flushed before beginning the fused-multiply-add computation, and Inexact may be signaled.

I.e. Inexact may be signaled both by input flushing and/or by the fused-multiply-add: the conditions or ORed.

Exceptions:

Coproprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Unimplemented Operation, Invalid Operation, Overflow, Underflow

The instructions `MAX.fmt`/`MIN.fmt`/`MAXA.fmt`/`MINA.fmt` correspond to the IEEE 754-2008 operations `maxNum`/`minNum`/`maxNumMag`/`minNumMag`.

- `MAX.fmt` corresponds to the IEEE 754-2008 operation `maxNum`.
- `MIN.fmt` corresponds to the IEEE 754-2008 operation `minNum`.
- `MAXA.fmt` corresponds to the IEEE 754-2008 operation `maxNumMag`.
- `MINA.fmt` corresponds to the IEEE 754-2008 operation `minNumMag`.

Numbers are preferred to NaNs: if one input is a NaN, but not both, the value of the numeric input is returned. If both are NaNs, the NaN in `fs` is returned.¹

The scalar FPU instructions `MAX.fmt`/`MIN.fmt`/`MAXA.fmt`/`MINA.fmt` correspond to the MSA instructions `FMAX.df`/`FMIN.df`/`FMAXA.df`/`FMINA.df`.

- Scalar FPU instruction `MAX.fmt` corresponds to the MSA vector instruction `FMAX.df`.
- Scalar FPU instruction `MIN.fmt` corresponds to the MSA vector instruction `FMIN.df`.
- Scalar FPU instruction `MAXA.fmt` corresponds to the MSA vector instruction `FMAX_A.df`.
- Scalar FPU instruction `MINA.fmt` corresponds to the MSA vector instruction `FMIN_A.df`.

Restrictions:

Data-dependent exceptions are possible as specified by the IEEE Standard for Floating-Point Arithmetic 754TM-2008. See also the section “Special Cases”, below.

Availability and Compatibility:

These instructions are introduced by and required as of Release 6.

Operation:

```

if not IsCoprocesorEnabled(1)
    then SignalException(CoprocesorUnusable, 1) endif
if not IsFloatingPointImplemented(fmt)
    then SignalException(ReservedInstruction) endif

v1 ← ValueFPR(fs, fmt)
v2 ← ValueFPR(ft, fmt)

if SNaN(v1) or SNaN(v2) then
    then SignalException(InvalidOperand) endif

if NaN(v1) and NaN(v2) then
    ftmp ← v1
elseif NaN(v1) then
    ftmp ← v2
elseif NaN(v2) then

```

1. IEEE standard 754-2008 allows either input to be chosen if both inputs are NaNs. Release 6 specifies that the first input must be propagated.

```

    ftmp ← v1
else
    case instruction of
    FMAX.fmt:    ftmp ← MaxFP.fmt (ValueFPR(fs,fmt), ValueFPR(ft,fmt))
    FMIN.fmt:    ftmp ← MinFP.fmt (ValueFPR(fs,fmt), ValueFPR(ft,fmt))
    FMAXA.fmt:   ftmp ← MaxAbsoluteFP.fmt (ValueFPR(fs,fmt), ValueFPR(ft,fmt))
    FMINA.fmt:   ftmp ← MinAbsoluteFP.fmt (ValueFPR(fs,fmt), ValueFPR(ft,fmt))
    end case
endif

StoreFPR (fd, fmt, ftmp)
/* end of instruction */

function MaxFP(tt, ts, n)
    /* Returns the largest argument. */
endfunction MaxFP

function MinFP(tt, ts, n)
    /* Returns the smallest argument. */
endfunction MinFP

function MaxAbsoluteFP(tt, ts, n)
    /* Returns the argument with largest absolute value.
       For equal absolute values, returns the largest positive argument.*/

MIPS32
MIPS32

Purpose: Move from Coprocessor 0

To move the contents of a coprocessor 0 register to a general register.

Description: $GPR[rt] \leftarrow CPR[0, rd, sel]$

The contents of the coprocessor 0 register specified by the combination of *rd* and *sel* are loaded into general register *rt*. Not all coprocessor 0 registers support the *sel* field. In those instances, the *sel* field must be zero.

Restrictions:

The results are **UNDEFINED** if coprocessor 0 does not contain a register as specified by *rd* and *sel*.

Operation:

```
reg = rd
data ← CPR[0, reg, sel]
GPR[rt] ← data
```

Exceptions:

Coprocessor Unusable

Reserved Instruction

Format: MFC1 *rt*, *fs*

MIPS32

Purpose: Move Word From Floating Point

To copy a word from an FPU (CP1) general register to a GPR.

Description: $\text{GPR}[\text{rt}] \leftarrow \text{FPR}[\text{fs}]$

The contents of FPR *fs* are loaded into general register *rt*.

Restrictions:

Operation:

```
data ← ValueFPR(fs, UNINTERPRETED_WORD)
GPR[rt] ← data
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Historical Information:

For MIPS I, MIPS II, and MIPS III the contents of GPR *rt* are **UNPREDICTABLE** for the instruction immediately following MFC1.

31	26	25	21	20	16	15	11	10	8	7	0

6			5		5						

Format: MFC2 rt, Impl
MFC2, rt, Impl, sel

MIPS32
MIPS32

The syntax shown above is an example using MFC1 as a model. The specific syntax is implementation dependent.

Purpose: Move Word From Coprocessor 2

To copy a word from a COP2 general register to a GPR.

Description: $GPR[rt] \leftarrow CP2CPR[Impl]$

The contents of the coprocessor 2 register denoted by the *Impl* field are and placed into general register *rt*. The interpretation of the *Impl* field is left entirely to the Coprocessor 2 implementation and is not specified by the architecture.

Restrictions:

The results are **UNPREDICTABLE** if the *Impl* field specifies a coprocessor 2 register that does not exist.

Operation:

$data \leftarrow CP2CPR[Impl]$
 $GPR[rt] \leftarrow data$

Exceptions:

Coprocessor Unusable

Format: MFHC0 rt, rd
MFHC0 rt, rd, sel

MIPS32 Release 5
MIPS32 Release 5

Purpose: Move from High Coprocessor 0

To move the contents of the upper 32 bits of a Coprocessor 0 register, extended by 32-bits, to a general register.

Description: $GPR[rt] \leftarrow CPR[0,rd,sel][63:32]$

The contents of the Coprocessor 0 register specified by the combination of *rd* and *sel* are loaded into general register *rt*. Not all Coprocessor 0 registers support the *sel* field, and in those instances, the *sel* field must be zero.

Restrictions:

The results are **UNDEFINED** if Coprocessor 0 does not contain a register as specified by *rd* and *sel*, or the register exists but is not extended by 32-bits, or the register is extended for XPA, but XPA is not supported or enabled.

Operation:

```
reg ← rd
data ← CPR[0,reg,sel]
GPR[rt] ← data63..32
```

Exceptions:

Coprocessor Unusable

Reserved Instruction

Format: MFHC1 rt, fs

MIPS32 Release 2

Purpose: Move Word From High Half of Floating Point Register

To copy a word from the high half of an FPU (CP1) general register to a GPR.

Description: $\text{GPR}[\text{rt}] \leftarrow \text{FPR}[\text{fs}]_{63..32}$

The contents of the high word of FPR *fs* are loaded into general register *rt*. This instruction is primarily intended to support 64-bit floating point units on a 32-bit CPU, but the semantics of the instruction are defined for all cases.

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

The results are **UNPREDICTABLE** if $\text{Status}_{FR} = 0$ and *fs* is odd.

Operation:

```
data ← ValueFPR(fs, UNINTERPRETED_DOUBLEWORD)_{63..32}
GPR[rt] ← data
```

Exceptions:

Coprocessor Unusable

Reserved Instruction

Format: MFHC2 rt, Impl
MFHC2, rt, rd, sel

MIPS32 Release 2
MIPS32 Release 2

The syntax shown above is an example using MFHC1 as a model. The specific syntax is implementation dependent.

Purpose: Move Word From High Half of Coprocessor 2 Register

To copy a word from the high half of a COP2 general register to a GPR.

Description: $GPR[rt] \leftarrow CP2CPR[Impl]_{63..32}$

The contents of the high word of the coprocessor 2 register denoted by the *Impl* field are placed into GPR *rt*. The interpretation of the *Impl* field is left entirely to the Coprocessor 2 implementation and is not specified by the architecture.

Restrictions:

The results are **UNPREDICTABLE** if the *Impl* field specifies a coprocessor 2 register that does not exist, or if that register is not 64 bits wide.

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

```
data ← CP2CPR[Impl]63..32
GPR[rt] ← data
```

Exceptions:

Coprocessor Unusable

Reserved Instruction

Format: MFHI rd

MIPS32, removed in Release 6

Purpose: Move From HI Register

To copy the special purpose *HI* register to a GPR.

Description: $\text{GPR}[\text{rd}] \leftarrow \text{HI}$

The contents of special register *HI* are loaded into GPR *rd*.

Restrictions:

None

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

$\text{GPR}[\text{rd}] \leftarrow \text{HI}$

Exceptions:

None

Historical Information:

In the MIPS I, II, and III architectures, the two instructions which follow the MFHI must not modify the *HI* register. If this restriction is violated, the result of the MFHI is **UNPREDICTABLE**. This restriction was removed in MIPS IV and MIPS32, and all subsequent levels of the architecture.

31	26	25	16	15	11	10	6	5	0
SPECIAL 000000			0 00 0000 0000			rd	0 00000		
6			10			5	5		
							MFLO 010010		
							6		

Format: MFLO rd

MIPS32, removed in Release 6

Purpose: Move From LO Register

To copy the special purpose *LO* register to a GPR.

Description: $\text{GPR}[\text{rd}] \leftarrow \text{LO}$

The contents of special register *LO* are loaded into GPR *rd*.

Restrictions:

None

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

$\text{GPR}[\text{rd}] \leftarrow \text{LO}$

Exceptions:

None

Historical Information:

In the MIPS I, II, and III architectures, the two instructions which follow the MFLO must not modify the *HI* register. If this restriction is violated, the result of the MFLO is **UNPREDICTABLE**. This restriction was removed in MIPS IV and MIPS32, and all subsequent levels of the architecture.

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt		0 00000		fs		fd		MOV 000110		
6	5		5		5		5		6		

Format: MOV.fmt

MOV.S fd, fs

MOV.D fd, fs

MOV.PS fd, fs

MIPS32

MIPS32

MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Move

To move an FP value between FPRs.

Description: $FPR[fd] \leftarrow FPR[fs]$

The value in FPR *fs* is placed into FPR *fd*. The source and destination are values in format *fmt*. In paired-single format, both the halves of the pair are copied to *fd*.

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs* and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of MOV.PS is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

The MOV.PS instruction has been removed in Release 6.

Operation:

StoreFPR(fd, fmt, ValueFPR(fs, fmt))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation

31	26	25	21	20	18	17	16	15	11	10	6	5	0
SPECIAL 000000		rs		cc		0 0	tf 0	rd		0 00000		MOVCI 000001	
6		5		3		1	1	5		5		6	

Format: MOVF rd, rs, cc

MIPS32, removed in Release 6

Purpose: Move Conditional on Floating Point False

To test an FP condition code then conditionally move a GPR.

Description: if FPConditionCode(cc) = 0 then GPR[rd] ← GPR[rs]

If the floating point condition code specified by CC is zero, then the contents of GPR rs are placed into GPR rd.

Restrictions:

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```
if FPConditionCode(cc) = 0 then
    GPR[rd] ← GPR[rs]
endif
```

Exceptions:

Reserved Instruction, Coprocessor Unusable

Format: MOVF.fmt

MOVF.S fd, fs, cc

MOVF.PS fd, fs, cc

MIPS32, removed in Release 6

MIPS32, removed in Release 6

removed in Release 6

MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Move Conditional on Floating Point False

To test an FP condition code then conditionally move an FP value.

Description: if FPConditionCode(cc) = 0 then FPR[fd] ← FPR[fs]

If the floating point condition code specified by *CC* is zero, then the value in FPR *fs* is placed into FPR *fd*. The source and destination are values in format *fmt*.

If the condition code is not zero, then FPR *fs* is not copied and FPR *fd* retains its previous value in format *fmt*. If *fd* did not contain a value either in format *fmt* or previously unused data from a load or move-to operation that could be interpreted in format *fmt*, then the value of *fd* becomes **UNPREDICTABLE**.

MOV.F.PS merges the lower half of FPR *fs* into the lower half of FPR *fd* if condition code *CC* is zero, and independently merges the upper half of FPR *fs* into the upper half of FPR *fd* if condition code *CC*+1 is zero. The *CC* field must be even; if it is odd, the result of this operation is **UNPREDICTABLE**.

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs* and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**. The operand must be a value in format *fmt*. If it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of MOV.F.PS is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

This instruction has been removed in Release 6 and has been replaced by the 'SEL.fmt' instruction. Refer to the SEL.fmt instruction in this manual for more information. Release 6 does not support Paired Single (PS).

Operation:

```
if FPConditionCode(cc) = 0 then
    StoreFPR(fd, fmt, ValueFPR(fs, fmt))
else
    StoreFPR(fd, fmt, ValueFPR(fd, fmt))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation

Format: MOVN rd, rs, rt

MIPS32, removed in Release 6

Purpose: Move Conditional on Not Zero

To conditionally move a GPR after testing a GPR value.

Description: if GPR[rt] \neq 0 then GPR[rd] \leftarrow GPR[rs]

If the value in GPR *rt* is not equal to zero, then the contents of GPR *rs* are placed into GPR *rd*.

Restrictions:

None

Availability and Compatibility:

This instruction has been removed in Release 6 and has been replaced by the ‘SELNEZ’ instruction. Refer to the SELNEZ instruction in this manual for more information.

Operation:

```

if GPR[rt]  $\neq$  0 then
    GPR[rd]  $\leftarrow$  GPR[rs]
endif
    
```

Exceptions:

None

Programming Notes:

The non-zero value tested might be the *condition true* result from the SLT, SLTI, SLTU, and SLTIU comparison instructions or a boolean value read from memory.

Format: MSUB *rs*, *rt*

MIPS32, removed in Release 6

Purpose: Multiply and Subtract Word to Hi, Lo

To multiply two words and subtract the result from *HI*, *LO*.

Description: $(HI, LO) \leftarrow (HI, LO) - (GPR[rs] \times GPR[rt])$

The 32-bit word value in GPR *rs* is multiplied by the 32-bit value in GPR *rt*, treating both operands as signed values, to produce a 64-bit result. The product is subtracted from the 64-bit concatenated values of *HI* and *LO*. The most significant 32 bits of the result are written into *HI* and the least significant 32 bits are written into *LO*. No arithmetic exception occurs under any circumstances.

Restrictions:

No restrictions in any architecture releases except Release 6.

This instruction does not provide the capability of writing directly to a target GPR.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```
temp ← (HI || LO) - (GPR[rs] × GPR[rt])
HI ← temp63..32
LO ← temp31..0
```

Exceptions:

None

Programming Notes:

Where the size of the operands are known, software should place the shorter operand in GPR *rt*. This may reduce the latency of the instruction on those processors which implement data-dependent instruction latencies.

31	26	25	21	20	16	15	11	10	6	5	3	2	0
COP1X 010011		fr		ft		fs		fd		MSUB 101		fmt	
6		5		5		5		5		3		3	

Format: MSUB.fmt

 MSUB.D fd, fr, fs, ft
 MSUB.PS fd, fr, fs, ft

MIPS32 Release 2, removed in Release 6
 MIPS32 Release 2, removed in Release 6
 MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Multiply Subtract

To perform a combined multiply-then-subtract of FP values.

Description: $FPR[fd] \leftarrow (FPR[fs] \times FPR[ft]) - FPR[fr]$

The value in FPR *fs* is multiplied by the value in FPR *ft* to produce an intermediate product. The intermediate product is rounded according to the current rounding mode in *FCSR*. The subtraction result is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operands and result are values in format *fmt*. The results and flags are as if separate floating-point multiply and subtract instructions were executed.

MSUB.PS multiplies then subtracts the upper and lower halves of FPR *fr*, FPR *fs*, and FPR *ft* independently, and ORs together any generated exceptional conditions.

The *Cause* bits are ORed into the *Flag* bits if no exception is taken.

Restrictions:

The fields *fr*, *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of MSUB.PS is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

MSUB.S and MSUB.D: Required in all versions of MIPS64 since MIPS64 Release 1. Not available in MIPS32 Release 1. Required in MIPS32 Release 2 and all subsequent versions of MIPS32. When required, these instructions are to be implemented if an FPU is present either in a 32-bit or 64-bit FPU or in a 32-bit or 64-bit FP Register Mode (*FIR*_{F64}=0 or 1, *Status*_{FR}=0 or 1).

This instruction has been removed in Release 6 and has been replaced by the fused multiply-subtract instruction. Refer to the fused multiply-subtract instruction ‘MSUBF.fmt’ in this manual for more information. Release 6 does not support Paired Single (PS).

Operation:

```
vfr ← ValueFPR(fr, fmt)
vfs ← ValueFPR(fs, fmt)
vft ← ValueFPR(ft, fmt)
StoreFPR(fd, fmt, (vfs ×fmt vft) -fmt vfr)
```

Exceptions:

6		5		5		5		5		6	

Format: MSUBU *rs*, *rt*

MIPS32, removed in Release 6

Purpose: Multiply and Subtract Word to Hi,Lo

To multiply two words and subtract the result from *HI*, *LO*.

Description: $(HI, LO) \leftarrow (HI, LO) - (GPR[rs] \times GPR[rt])$

The 32-bit word value in GPR *rs* is multiplied by the 32-bit word value in GPR *rt*, treating both operands as unsigned values, to produce a 64-bit result. The product is subtracted from the 64-bit concatenated values of *HI* and *LO*. The most significant 32 bits of the result are written into *HI* and the least significant 32 bits are written into *LO*. No arithmetic exception occurs under any circumstances.

Restrictions:

This instruction does not provide the capability of writing directly to a target GPR.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```
temp ← (HI || LO) - (GPR[rs] × GPR[rt])
HI ← temp63..32
LO ← temp31..0
```

Exceptions:

None

Programming Notes:

Where the size of the operands are known, software should place the shorter operand in GPR *rt*. This may reduce the latency of the instruction on those processors which implement data-dependent instruction latencies.

Format: MTC0 rt, rd
MTC0 rt, rd, sel

MIPS32
MIPS32

Purpose: Move to Coprocessor 0

To move the contents of a general register to a coprocessor 0 register.

Description: $CPR[0, rd, sel] \leftarrow GPR[rt]$

The contents of general register *rt* are loaded into the coprocessor 0 register specified by the combination of *rd* and *sel*. Not all coprocessor 0 registers support the *sel* field. In those instances, the *sel* field must be set to zero.

In Release 5, for a 32-bit processor, the MTC0 instruction writes all zeroes to the high-order bits of selected COP0 registers that have been extended beyond 32 bits. This is required for compatibility with legacy software that does not use MTHC0, yet has hardware support for extended COP0 registers (such as for Extended Physical Addressing (XPA)). Because MTC0 overwrites the result of MTHC0, software must first read the high-order bits before writing the low-order bits, then write the high-order bits back either modified or unmodified. For initialization of an extended register, software may first write the low-order bits, then the high-order bits, without first reading the high-order bits.

Restrictions:

The results are **UNDEFINED** if coprocessor 0 does not contain a register as specified by *rd* and *sel*.

Operation:

```

data ← GPR[rt]
reg ← rd
if (Config5MVH = 1) then
    // The most-significant bit may vary by register. Only supported
    // bits should be written 0.
    // Extended LLAddr is not written with 0s, as it is a read-only register.
    // BadVAddr is not written with 0s, as it is read-only
    if (Config3LPA = 1) then
        if (reg, sel = EntryLo0 or EntryLo1) then CPR[0, reg, sel]63:32 = 032
        if (reg, sel = MAAR) then CPR[0, reg, sel]63:32 = 032
        // TagLo is zeroed only if the implementation-dependent bits are
        // writeable
        if (reg, sel = TagLo) then CPR[0, reg, sel]63:32 = 032
        if (Config3VZ = 1) then
            if (reg, sel = EntryHi) then CPR[0, reg, sel]63:32 = 032
        endif
    endif
endif
endif

```

Exceptions:

Coprocessor Unusable

Reserved Instruction

Format: MTC1 *rt*, *fs*

MIPS32

Purpose: Move Word to Floating Point

To copy a word from a GPR to an FPU (CP1) general register.

Description: $\text{FPR}[\text{fs}] \leftarrow \text{GPR}[\text{rt}]$

The low word in GPR *rt* is placed into the low word of FPR *fs*.

Restrictions:

Operation:

```
data ← GPR[rt]31..0
StoreFPR(fs, UNINTERPRETED_WORD, data)
```

Exceptions:

Coprocessor Unusable

Historical Information:

For MIPS I, MIPS II, and MIPS III the value of FPR *fs* is **UNPREDICTABLE** for the instruction immediately following MTC1.

31	26	25	21	20	16	15	11	10	8	7	0

MTHC0 rt, rd, sel

MIPS32 Release 5
MIPS32 Release 5

Purpose: Move to High Coprocessor 0

To copy a word from a GPR to the upper 32 bits of a COP2 general register that has been extended by 32 bits.

Description: $\text{CPR}[0, \text{rd}, \text{sel}][63:32] \leftarrow \text{GPR}[\text{rt}]$

The contents of general register *rt* are loaded into the Coprocessor 0 register specified by the combination of *rd* and *sel*. Not all Coprocessor 0 registers support the *sel* field; the *sel* field must be set to zero.

Restrictions:

The results are **UNDEFINED** if Coprocessor 0 does not contain a register as specified by *rd* and *sel*, or if the register exists but is not extended by 32 bits, or the register is extended for XPA, but XPA is not supported or enabled.

Operation:

```
data ← GPR[rt]
reg ← rd
CPR[0, reg, sel][63:32] ← data
```

Exceptions:

Coprocessor Unusable

Reserved Instruction

Format: MTHC1 rt, fs

MIPS32 Release 2

Purpose: Move Word to High Half of Floating Point Register

To copy a word from a GPR to the high half of an FPU (CP1) general register.

Description: $\text{FPR}[\text{fs}]_{63..32} \leftarrow \text{GPR}[\text{rt}]$

The word in GPR *rt* is placed into the high word of FPR *fs*. This instruction is primarily intended to support 64-bit floating point units on a 32-bit CPU, but the semantics of the instruction are defined for all cases.

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

The results are **UNPREDICTABLE** if $\text{Status}_{FR} = 0$ and *fs* is odd.

Operation:

```
newdata ← GPR[rt]
olddata ← ValueFPR(fs, UNINTERPRETED_DOUBLEWORD)_{31..0}
StoreFPR(fs, UNINTERPRETED_DOUBLEWORD, newdata || olddata)
```

Exceptions:

Coprocessor Unusable

Reserved Instruction

Programming Notes

When paired with MTC1 to write a value to a 64-bit FPR, the MTC1 must be executed first, followed by the MTHC1. This is because of the semantic definition of MTC1, which is not aware that software is using an MTHC1 instruction to complete the operation, and sets the upper half of the 64-bit FPR to an **UNPREDICTABLE** value.

Format: MTHC2 rt, Impl
MTHC2 rt, Impl, sel

MIPS32 Release 2
MIPS32 Release 2

The syntax shown above is an example using MTHC1 as a model. The specific syntax is implementation dependent.

Purpose: Move Word to High Half of Coprocessor 2 Register

To copy a word from a GPR to the high half of a COP2 general register.

Description: $CP2CPR[Impl]_{63..32} \leftarrow GPR[rt]$

The word in GPR *rt* is placed into the high word of coprocessor 2 general register denoted by the *Impl* field. The interpretation of the *Impl* field is left entirely to the Coprocessor 2 implementation and is not specified by the architecture.

Restrictions:

The results are **UNPREDICTABLE** if the *Impl* field specifies a coprocessor 2 register that does not exist, or if that register is not 64 bits wide.

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

```
data ← GPR[rt]
CP2CPR[Impl] ← data || CPR[2,rd,sel]_{31..0}
```

Exceptions:

Coprocessor Unusable

Reserved Instruction

Programming Notes

When paired with MTC2 to write a value to a 64-bit CPR, the MTC2 must be executed first, followed by the MTHC2. This is because of the semantic definition of MTC2, which is not aware that software is using an MTHC2 instruction to complete the operation, and sets the upper half of the 64-bit CPR to an **UNPREDICTABLE** value.

Format: MTHI rs

MIPS32, removed in Release 6

Purpose: Move to HI Register

To copy a GPR to the special purpose *HI* register.

Description: $HI \leftarrow GPR[rs]$

The contents of GPR *rs* are loaded into special register *HI*.

Restrictions:

A computed result written to the *HI/LO* pair by DIV, DIVU, MULT, or MULTU must be read by MFHI or MFLO before a new result can be written into either *HI* or *LO*.

If an MTHI instruction is executed following one of these arithmetic instructions, but before an MFLO or MFHI instruction, the contents of *LO* are **UNPREDICTABLE**. The following example shows this illegal situation:

```

MULT   r2,r4 # start operation that will eventually write to HI,LO
...    # code not containing mfhi or mflo
MTHI   r6
...    # code not containing mflo
MFLO   r3    # this mflo would get an UNPREDICTABLE value

```

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

$HI \leftarrow GPR[rs]$

Exceptions:

None

Historical Information:

In MIPS I-III, if either of the two preceding instructions is MFHI, the result of that MFHI is **UNPREDICTABLE**. Reads of the *HI* or *LO* special register must be separated from any subsequent instructions that write to them by two or more instructions. In MIPS IV and later, including MIPS32, this restriction does not exist.

Format: MTLO rs

MIPS32, removed in Release 6

Purpose: Move to LO Register

To copy a GPR to the special purpose *LO* register.

Description: $LO \leftarrow GPR[rs]$

The contents of GPR *rs* are loaded into special register *LO*.

Restrictions:

A computed result written to the *HI/LO* pair by DIV, DIVU, MULT, or MULTU must be read by MFHI or MFLO before a new result can be written into either *HI* or *LO*.

If an MTLO instruction is executed following one of these arithmetic instructions, but before an MFLO or MFHI instruction, the contents of *HI* are **UNPREDICTABLE**. The following example shows this illegal situation:

```

MULT   r2,r4 # start operation that will eventually write to HI,LO
...    # code not containing mfhi or mflo
MTLO   r6
...    # code not containing mfhi
MFHI   r3    # this mfhi would get an UNPREDICTABLE value

```

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

$LO \leftarrow GPR[rs]$

Exceptions:

None

Historical Information:

In MIPS I-III, if either of the two preceding instructions is MFHI, the result of that MFHI is **UNPREDICTABLE**. Reads of the *HI* or *LO* special register must be separated from any subsequent instructions that write to them by two or more instructions. In MIPS IV and later, including MIPS32, this restriction does not exist.

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL2 011100	rs	rt	rd						0 00000	MUL 000010	
6	5	5	5						5	6	

Format: MUL rd, rs, rt

MIPS32, removed in Release 6

Purpose: Multiply Word to GPR

To multiply two words and write the result to a GPR.

Description: $GPR[rd] \leftarrow GPR[rs] \times GPR[rt]$

The 32-bit word value in GPR *rs* is multiplied by the 32-bit value in GPR *rt*, treating both operands as signed values, to produce a 64-bit result. The least significant 32 bits of the product are written to GPR *rd*. The contents of *HI* and *LO* are **UNPREDICTABLE** after the operation. No arithmetic exception occurs under any circumstances.

Restrictions:

Note that this instruction does not provide the capability of writing the result to the *HI* and *LO* registers.

Availability and Compatibility:

The pre-Release 6 MUL instruction has been removed in Release 6. It has been replaced by a similar instruction of the same mnemonic, MUL, but different encoding, which is a member of a family of single-width multiply instructions. Refer to the ‘MUL’ and ‘MUH’ instructions in this manual for more information.

Operation:

```
temp ← GPR[rs] × GPR[rt]
GPR[rd] ← temp31..0
HI ← UNPREDICTABLE
LO ← UNPREDICTABLE
```

Exceptions:

None

Programming Notes:

In some processors the integer multiply operation may proceed asynchronously and allow other CPU instructions to execute before it is complete. An attempt to read GPR *rd* before the results are written interlocks until the results are ready. Asynchronous execution does not affect the program result, but offers an opportunity for performance improvement by scheduling the multiply so that other instructions can execute in parallel.

Programs that require overflow detection must check for it explicitly.

Where the size of the operands are known, software should place the shorter operand in GPR *rt*. This may reduce the latency of the instruction on those processors which implement data-dependent instruction latencies.

31	26	25	21	20	16	15	11	10	6	5	0

MUH rd,rs,rt
MULU rd,rs,rt
MUHU rd,rs,rt

MIPS32 Release 6
MIPS32 Release 6
MIPS32 Release 6
MIPS32 Release 6

Purpose: Multiply Integers (with result to GPR)

MUL: Multiply Words Signed, Low Word
MUH: Multiply Words Signed, High Word
MULU: Multiply Words Signed, Low Word
MUHU: Multiply Words Signed, High Word

Description:

MUL: $GPR[rd] \leftarrow \text{sign_extend.32}(\text{lo_word}(\text{multiply.signed}(GPR[rs] \times GPR[rt]))$
MUH: $GPR[rd] \leftarrow \text{sign_extend.32}(\text{hi_word}(\text{multiply.signed}(GPR[rs] \times GPR[rt]))$
MULU: $GPR[rd] \leftarrow \text{sign_extend.32}(\text{lo_word}(\text{multiply.unsigned}(GPR[rs] \times GPR[rt]))$
MUHU: $GPR[rd] \leftarrow \text{sign_extend.32}(\text{hi_word}(\text{multiply.unsigned}(GPR[rs] \times GPR[rt]))$

The Release 6 multiply instructions multiply the operands in GPR[rs] and GPR[rd], and place the specified high or low part of the result, of the same width, in GPR[rd].

MUL performs a signed 32-bit integer multiplication, and places the low 32 bits of the result in the destination register.

MUH performs a signed 32-bit integer multiplication, and places the high 32 bits of the result in the destination register.

MULU performs an unsigned 32-bit integer multiplication, and places the low 32 bits of the result in the destination register.

MUHU performs an unsigned 32-bit integer multiplication, and places the high 32 bits of the result in the destination register.

Restrictions:

MUL behaves correctly even if its inputs are not sign extended 32-bit integers. Bits 32-63 of its inputs do not affect the result.

MULU behaves correctly even if its inputs are not zero or sign extended 32-bit integers. Bits 32-63 of its inputs do not affect the result.

Availability and Compatibility:

These instructions are introduced by and required as of Release 6.

Programming Notes:

The low half of the integer multiplication result is identical for signed and unsigned. Nevertheless, there are distinct instructions MUL MULU . Implementations may choose to optimize a multiply that produces the low half followed by a multiply that produces the upper half. Programmers are recommended to use matching lower and upper half multiplications.

Release 6 MUL instruction has the same opcode mnemonic as the pre-Release 6 MUL instruction. The semantics of these instructions are almost identical: both produce the low 32-bits of the 32×32=64 product; but the pre-Release 6 MUL is unpredictable if its inputs are not properly sign extended 32-bit values on a 64 bit machine, and is defined to render the HI and LO registers unpredictable, whereas the Release 6 version ignores bits 32-63 of the input, and there are no HI/LO registers in Release 6 to be affected. If disambiguation is necessary, say Release 6 versus pre-Release 6 or specify the instruction string.

Operation:

```

MUH: if NotWordValue(GPR[rs]) then UNPREDICTABLE endif
MUH: if NotWordValue(GPR[rt]) then UNPREDICTABLE endif
MUHU: if not(zero_or_sign_extended.32(GPR[rs])) then UNPREDICTABLE endif
MUHU: if not(zero_or_sign_extended.32(GPR[rt])) then UNPREDICTABLE endif

/* recommended implementation: ignore bits 32-63 for MUL, MUH, MULU, MUHU */

MUL, MUH:
    s1 ← signed_word(GPR[rs])
    s2 ← signed_word(GPR[rt])
MULU, MUHU:
    s1 ← unsigned_word(GPR[rs])
    s2 ← unsigned_word(GPR[rt])

product ← s1 × s2      /* product is twice the width of sources */

MUL:   GPR[rd] ← sign_extend.32( lo_word( product ) )
MUH:   GPR[rd] ← sign_extend.32( hi_word( product ) )
MULU:  GPR[rd] ← sign_extend.32( lo_word( product ) )
MUHU:  GPR[rd] ← sign_extend.32( hi_word( product ) )
endif

```

Exceptions:

None

Format: MUL.fmt
MUL.S fd, fs, ft
MUL.D fd, fs, ft
MUL.PS fd, fs, ft

MIPS32
MIPS32
MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Multiply

To multiply FP values.

Description: $FPR[fd] \leftarrow FPR[fs] \times FPR[ft]$

The value in FPR *fs* is multiplied by the value in FPR *ft*. The result is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operands and result are values in format *fmt*. MUL.PS multiplies the upper and lower halves of FPR *fs* and FPR *ft* independently, and ORs together any generated exceptional conditions.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of MUL.PS is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

The MUL.PS instruction has been removed in Release 6.

Operation:

StoreFPR (fd, fmt, ValueFPR(fs, fmt) \times_{fmt} ValueFPR(ft, fmt))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Unimplemented Operation, Invalid Operation, Overflow, Underflow

Format: MULT rs, rt

MIPS32, removed in Release 6

Purpose: Multiply Word

To multiply 32-bit signed integers.

Description: (HI, LO) \leftarrow GPR[rs] \times GPR[rt]

The 32-bit word value in GPR *rt* is multiplied by the 32-bit value in GPR *rs*, treating both operands as signed values, to produce a 64-bit result. The low-order 32-bit word of the result is placed into special register *LO*, and the high-order 32-bit word is placed into special register *HI*.

No arithmetic exception occurs under any circumstances.

Restrictions:

None

Availability and Compatibility:

The MULT instruction has been removed in Release 6. It has been replaced by the Multiply Low (MUL) and Multiply High (MUH) instructions, whose output is written to a single GPR. Refer to the ‘MUL’ and ‘MUH’ instructions in this manual for more information.

Operation:

```

prod  $\leftarrow$  GPR[rs]31..0  $\times$  GPR[rt]31..0
LO  $\leftarrow$  prod31..0
HI  $\leftarrow$  prod63..32

```

Exceptions:

None

Programming Notes:

In some processors the integer multiply operation may proceed asynchronously and allow other CPU instructions to execute before it is complete. An attempt to read *LO* or *HI* before the results are written interlocks until the results are ready. Asynchronous execution does not affect the program result, but offers an opportunity for performance improvement by scheduling the multiply so that other instructions can execute in parallel.

Programs that require overflow detection must check for it explicitly.

Where the size of the operands are known, software should place the shorter operand in GPR *rt*. This may reduce the latency of the instruction on those processors which implement data-dependent instruction latencies.

Implementation Note:

Format: MULTU *rs*, *rt*

MIPS32, removed in Release 6

Purpose: Multiply Unsigned Word

To multiply 32-bit unsigned integers.

Description: $(HI, LO) \leftarrow GPR[rs] \times GPR[rt]$

The 32-bit word value in GPR *rt* is multiplied by the 32-bit value in GPR *rs*, treating both operands as unsigned values, to produce a 64-bit result. The low-order 32-bit word of the result is placed into special register *LO*, and the high-order 32-bit word is placed into special register *HI*.

No arithmetic exception occurs under any circumstances.

Restrictions:

None

Availability and Compatibility:

The MULTU instruction has been removed in Release 6. It has been replaced by the Multiply Low (MULU) and Multiply High (MUHU) instructions, whose output is written to a single GPR. Refer to the ‘MULU’ and ‘MUHU’ instructions in this manual for more information.

Operation:

```

prod ← (0 || GPR[rs]31..0) × (0 || GPR[rt]31..0)
LO ← prod31..0
HI ← prod63..32

```

Exceptions:

None

Programming Notes:

In some processors the integer multiply operation may proceed asynchronously and allow other CPU instructions to execute before it is complete. An attempt to read *LO* or *HI* before the results are written interlocks until the results are ready. Asynchronous execution does not affect the program result, but offers an opportunity for performance improvement by scheduling the multiply so that other instructions can execute in parallel.

Programs that require overflow detection must check for it explicitly.

Where the size of the operands are known, software should place the shorter operand in GPR *rt*. This may reduce the latency of the instruction on those processors which implement data-dependent instruction latencies.

31	26	25	21	20	16	15	0
REGIMM 000001		0 00000		NAL 10000		offset	
6		5		5		16	

Format: NAL

Assembly Idiom MIPS32, MIPS32 Release 6

Purpose: No-op and Link

Description: $\text{GPR}[31] \leftarrow \text{PC} + 8$

NAL is an instruction used to read the PC.

NAL was originally an alias for pre-Release 6 instruction BLTZAL. The condition is false, so the 16-bit target offset field is ignored, but the link register, GPR 31, is unconditionally written with the address of the instruction past the delay slot.

Restrictions:

NAL is considered to be a not-taken branch, with a delay slot, and may not be followed by instructions not allowed in delay slots. Nor is NAL allowed in a delay slot or forbidden slot.

Availability and Compatibility:

This is a deprecated instruction in Release 6. It is strongly recommended not to use this deprecated instructions because it will be removed from a future revision of the MIPS Architecture.

The pre-Release 6 instruction BLTZAL when rs is not GPR[0], is removed in Release 6, and is required to signal a Reserved Instruction exception. Release 6 adds BLTZALC, the equivalent compact conditional branch and link, with no delay slot.

This instruction, NAL, is introduced by and required as of Release 6, the mnemonic NAL becomes distinguished from the BLTZAL instruction removed in Release 6. The NAL instruction encoding, however, works on all implementations, both pre-Release 6, where it was a special case of BLEZAL, and Release 6, where it is an instruction in its own right.

NAL is provided only for compatibility with pre-Release 6 software. It is recommended that you use ADDIU to generate a PC-relative address.

Exceptions:

None¹

Operation:

$\text{GPR}[31] \leftarrow \text{PC} + 8$

1. Except for possible Reserved Instruction Exception if used in a Forbidden Slot, true of these and most other control transfer instructions (CTIs)

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt		0 00000		fs		fd		NEG 000111		
6	5		5		5		5		6		

Format: NEG.fmt

NEG.S fd, fs

NEG.D fd, fs

NEG.PS fd, fs

MIPS32

MIPS32

MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Negate

To negate an FP value.

Description: $FPR[fd] \leftarrow -FPR[fs]$

The value in FPR *fs* is negated and placed into FPR *fd*. The value is negated by changing the sign bit value. The operand and result are values in format *fmt*. NEG.PS negates the upper and lower halves of FPR *fs* independently, and ORs together any generated exceptional conditions.

If $FIR_{Has2008}=0$ or $FCSR_{ABS2008}=0$ then this operation is arithmetic. For this case, any NaN operand signals invalid operation.

If $FCSR_{ABS2008}=1$ then this operation is non-arithmetic. For this case, both regular floating point numbers and NaN values are treated alike, only the sign bit is affected by this instruction. No IEEE 754 exception can be generated for this case.

Restrictions:

The fields *fs* and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**. The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of NEG.PS is **UNPREDICTABLE** if the processor is executing in the $FR=0$ 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the $FR=1$ mode, but not with $FR=0$, and not on a 32-bit FPU.

Availability and Compatibility:

The NEG.PS instruction has been removed in Release 6.

Operation:

$StoreFPR(fd, fmt, Negate(ValueFPR(fs, fmt)))$

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation, Invalid Operation

MIPS32 Release 2, removed in Release 6
 MIPS32 Release 2, removed in Release 6
 MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Negative Multiply Add

To negate a combined multiply-then-add of FP values.

Description: $FPR[fd] \leftarrow -((FPR[fs] \times FPR[ft]) + FPR[fr])$

The value in FPR *fs* is multiplied by the value in FPR *ft* to produce an intermediate product. The intermediate product is rounded according to the current rounding mode in *FCSR*. The value in FPR *fr* is added to the product.

The result sum is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, negated by changing the sign bit, and placed into FPR *fd*. The operands and result are values in format *fmt*. The results and flags are as if separate floating-point multiply and add and negate instructions were executed.

NMADD.PS applies the operation to the upper and lower halves of FPR *fr*, FPR *fs*, and FPR *ft* independently, and ORs together any generated exceptional conditions.

The *Cause* bits are ORed into the *Flag* bits if no exception is taken.

Restrictions:

The fields *fr*, *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of NMADD.PS is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

This instruction has been removed in Release 6.

NMADD.S and NMADD.D: Required in all versions of MIPS64 since MIPS64 Release 1. Not available in MIPS32 Release 1. Required by MIPS32 Release 2 and subsequent versions of MIPS32. When required, these instructions are to be implemented if an FPU is present either in a 32-bit or 64-bit FPU or in a 32-bit or 64-bit FP Register Mode (*FIR*_{F64}=0 or 1, *Status*_{FR}=0 or 1).

Operation:

```
vfr ← ValueFPR(fr, fmt)
vfs ← ValueFPR(fs, fmt)
vft ← ValueFPR(ft, fmt)
StoreFPR(fd, fmt, -(vfr +fmt (vfs ×fmt vft)))
```

MIPS32 Release 2, removed in Release 6
 MIPS32 Release 2, removed in Release 6
 MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Negative Multiply Subtract

To negate a combined multiply-then-subtract of FP values.

Description: $FPR[fd] \leftarrow ((FPR[fs] \times FPR[ft]) - FPR[fr])$

The value in FPR *fs* is multiplied by the value in FPR *ft* to produce an intermediate product. The intermediate product is rounded according to the current rounding mode in *FCSR*. The value in FPR *fr* is subtracted from the product.

The result is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, negated by changing the sign bit, and placed into FPR *fd*. The operands and result are values in format *fmt*. The results and flags are as if separate floating-point multiply and subtract and negate instructions were executed.

NMSUB.PS applies the operation to the upper and lower halves of FPR *fr*, FPR *fs*, and FPR *ft* independently, and ORs together any generated exceptional conditions.

The *Cause* bits are ORed into the *Flag* bits if no exception is taken.

Restrictions:

The fields *fr*, *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of NMSUB.PS is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0 and not on a 32-bit FPU.

Availability and Compatibility:

This instruction has been removed in Release 6.

NMSUB.S and NMSUB.D: Required in all versions of MIPS64 since MIPS64 Release 1. Not available in MIPS32 Release 1. Required in MIPS32 Release 2 and all subsequent versions of MIPS32. When required, these instructions are to be implemented if an FPU is present either in a 32-bit or 64-bit FPU or in a 32-bit or 64-bit FP Register Mode (*FIR*_{F64}=0 or 1, *Status*_{FR}=0 or 1).

Operation:

```
vfr ← ValueFPR(fr, fmt)
vfs ← ValueFPR(fs, fmt)
vft ← ValueFPR(ft, fmt)
StoreFPR(fd, fmt, -((vfs ×fmt vft) -fmt vfr))
```

6	5	5	5	5	5	6						

Format: PAUSE

MIPS32 Release 2/MT Module

Purpose: Wait for the LLBit to clear.

Description:

Locks implemented using the LL/SC instructions are a common method of synchronization between threads of control. A lock implementation does a load-linked instruction and checks the value returned to determine whether the software lock is set. If it is, the code branches back to retry the load-linked instruction, implementing an active busy-wait sequence. The PAUSE instruction is intended to be placed into the busy-wait sequence to block the instruction stream until such time as the load-linked instruction has a chance to succeed in obtaining the software lock.

The PAUSE instruction is implementation-dependent, but it usually involves descheduling the instruction stream until the LLBit is zero.

- In a single-threaded processor, this may be implemented as a short-term WAIT operation which resumes at the next instruction when the LLBit is zero or on some other external event such as an interrupt.
- On a multi-threaded processor, this may be implemented as a short term YIELD operation which resumes at the next instruction when the LLBit is zero.

In either case, it is assumed that the instruction stream which gives up the software lock does so via a write to the lock variable, which causes the processor to clear the LLBit as seen by this thread of execution.

The encoding of the instruction is such that it is backward compatible with all previous implementations of the architecture. The PAUSE instruction can therefore be placed into existing lock sequences and treated as a NOP by the processor, even if the processor does not implement the PAUSE instruction.

Restrictions:

Pre-Release 6: The operation of the processor is **UNPREDICTABLE** if a PAUSE instruction is executed placed in the delay slot of a branch or jump instruction.

Release 6 implementations are required to signal a Reserved Instruction Exception if PAUSE is encountered in the delay slot or forbidden slot of a branch or jump instruction.

Operations:

```

if LLBit ≠ 0 then
    EPC ← PC + 4                /* Resume at the following instruction */
    DescheduleInstructionStream()
endif

```

Exceptions:

None

Programming Notes:

The PAUSE instruction is intended to be inserted into the instruction stream after an LL instruction has set the LLBit and found the software lock set. The program may wait forever if a PAUSE instruction is executed and there is no possibility that the LLBit will ever be cleared.

An example use of the PAUSE instruction is included in the following example:

```
acquire_lock:
    ll    t0, 0(a0)           /* Read software lock, set hardware lock */
    bnez  t0, acquire_lock_retry: /* Branch if software lock is taken */
    addiu t0, t0, 1           /* Set the software lock */
    sc    t0, 0(a0)           /* Try to store the software lock */
    bnez  t0, 10f             /* Branch if lock acquired successfully */
    sync
acquire_lock_retry:
    pause                               /* Wait for LLBIT to clear before retry */
    b     acquire_lock              /* and retry the operation */
    nop
10:

    Critical region code

release_lock:
    sync
    sw    zero, 0(a0)           /* Release software lock, clearing LLBIT */
                                /* for any PAUSEd waiters */
```

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt 10110		ft		fs		fd		PLL 101100		
6	5		5		5		5		6		

Format: PLL.PS *fd*, *fs*, *ft*

MIPS32 Release 2, removed in Release 6

Purpose: Pair Lower Lower

To merge a pair of paired single values with realignment.

Description: $\text{FPR}[\text{fd}] \leftarrow \text{lower}(\text{FPR}[\text{fs}]) \mid \mid \text{lower}(\text{FPR}[\text{ft}])$

A new paired-single value is formed by concatenating the lower single of FPR *fs* (bits **31..0**) and the lower single of FPR *ft* (bits **31..0**).

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *PS*. If the fields are not valid, the result is **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

$\text{StoreFPR}(\text{fd}, \text{PS}, \text{ValueFPR}(\text{fs}, \text{PS})_{31..0} \mid \mid \text{ValueFPR}(\text{ft}, \text{PS})_{31..0})$

MIPS32 Release 2, removed in Release 6

Purpose: Pair Lower Upper

To merge a pair of paired single values with realignment.

Description: $\text{FPR}[\text{fd}] \leftarrow \text{lower}(\text{FPR}[\text{fs}]) \parallel \text{upper}(\text{FPR}[\text{ft}])$

A new paired-single value is formed by catenating the lower single of FPR *fs* (bits **31..0**) and the upper single of FPR *ft* (bits **63..32**).

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *PS*. If the fields are not valid, the result is **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

$\text{StoreFPR}(\text{fd}, \text{PS}, \text{ValueFPR}(\text{fs}, \text{PS})_{31..0} \parallel \text{ValueFPR}(\text{ft}, \text{PS})_{63..32})$

Exceptions:

Coprocessor Unusable, Reserved Instruction

pre-Release 6

Release 6

Format: PREF hint,offset(base)

MIPS32

Purpose: Prefetch

To move data between memory and cache.

Description: prefetch_memory(GPR[base] + offset)

PREF adds the signed *offset* to the contents of GPR *base* to form an effective byte address. The *hint* field supplies information about the way that the data is expected to be used.

PREF enables the processor to take some action, typically causing data to be moved to or from the cache, to improve program performance. The action taken for a specific PREF instruction is both system and context dependent. Any action, including doing nothing, is permitted as long as it does not change architecturally visible state or alter the meaning of a program. Implementations are expected either to do nothing, or to take an action that increases the performance of the program. The PrepareForStore function is unique in that it may modify the architecturally visible state.

PREF does not cause addressing-related exceptions, including TLB exceptions. If the address specified would cause an addressing exception, the exception condition is ignored and no data movement occurs. However even if no data is moved, some action that is not architecturally visible, such as writeback of a dirty cache line, can take place.

It is implementation dependent whether a Bus Error or Cache Error exception is reported if such an error is detected as a byproduct of the action taken by the PREF instruction.

PREF neither generates a memory operation nor modifies the state of a cache line for a location with an *uncached* memory access type, whether this type is specified by the address segment (e.g., kseg1), the programmed cacheability and coherency attribute of a segment (e.g., the use of the *K0*, *KU*, or *K23* fields in the *Config* register), or the per-page cacheability and coherency attribute provided by the TLB.

If PREF results in a memory operation, the memory access type and cacheability&coherency attribute used for the operation are determined by the memory access type and cacheability&coherency attribute of the effective address, just as it would be if the memory operation had been caused by a load or store to the effective address.

For a cached location, the expected and useful action for the processor is to prefetch a block of data that includes the effective address. The size of the block and the level of the memory hierarchy it is fetched into are implementation specific.

In coherent multiprocessor implementations, if the effective address uses a coherent Cacheability and Coherency Attribute (CCA), then the instruction causes a coherent memory transaction to occur. This means a prefetch issued on one processor can cause data to be evicted from the cache in another processor.

The PREF instruction and the memory transactions which are sourced by the PREF instruction, such as cache refill or cache writeback, obey the ordering and completion rules of the SYNC instruction.

Table 5.2 Values of *hint* Field for PREF Instruction

Value	Name	Data Use and Desired Prefetch Action
0	load	Use: Prefetched data is expected to be read (not modified). Action: Fetch data as if for a load.
1	store	Use: Prefetched data is expected to be stored or modified. Action: Fetch data as if for a store.
2	L1 LRU hint	Pre-Release 6: Reserved for Architecture. Implementation dependent in Release 6. This hint code marks the line as LRU in the L1 cache and thus preferred for next eviction. Implementations can choose to writeback and/or invalidate as long as no architectural state is modified.
3	Reserved	Pre-Release 6: Reserved for Architecture. Release 6: Available for implementation dependent use.
4	load_streamed	Use: Prefetched data is expected to be read (not modified) but not reused extensively; it “streams” through cache. Action: Fetch data as if for a load and place it in the cache so that it does not displace data prefetched as “retained.”
5	store_streamed	Use: Prefetched data is expected to be stored or modified but not reused extensively; it “streams” through cache. Action: Fetch data as if for a store and place it in the cache so that it does not displace data prefetched as “retained.”
6	load_retained	Use: Prefetched data is expected to be read (not modified) and reused extensively; it should be “retained” in the cache. Action: Fetch data as if for a load and place it in the cache so that it is not displaced by data prefetched as “streamed.”
7	store_retained	Use: Prefetched data is expected to be stored or modified and reused extensively; it should be “retained” in the cache. Action: Fetch data as if for a store and place it in the cache so that it is not displaced by data prefetched as “streamed.”
8-15	Reserved	In the Release 6 architecture, hint codes 8 - 15 are treated the same as hint codes 0 - 7 respectively, but operate on the L2 cache.
16-23	Reserved	In the Release 6 architecture, hint codes 16 - 23 are treated the same as hint codes 0 - 7 respectively, but operate on the L3 cache.
24	Reserved	Pre-Release 6: Unassigned by the Architecture - available for implementation-dependent use. This hint code is not implemented in the Release 6 architecture and generates a Reserved Instruction exception (RI).
25	writeback_invalidate (also known as “nudge”) Reserved in Release 6	Use: Data is no longer expected to be used. Action: For a writeback cache, schedule a writeback of any dirty data. At the completion of the writeback, mark the state of any cache lines written back as invalid. If the cache line is not dirty, it is implementation dependent whether the state of the cache line is marked invalid or left unchanged. If the cache line is locked, no action is taken. This hint code is not implemented in the Release 6 architecture and generates a Reserved Instruction exception (RI).

Table 5.2 Values of *hint* Field for PREF Instruction

26-29	Reserved	Pre-Release 6: Unassigned by the Architecture — available for implementation-dependent use. These hints are not implemented in the Release 6 architecture and generate a Reserved Instruction exception (RI).
30	PrepareForStore Reserved in Release 6	Use: Prepare the cache for writing an entire line, without the overhead involved in filling the line from memory. Action: If the reference hits in the cache, no action is taken. If the reference misses in the cache, a line is selected for replacement, any valid and dirty victim is written back to memory, the entire line is filled with zero data, and the state of the line is marked as valid and dirty. Programming Note: Because the cache line is filled with zero data on a cache miss, software must not assume that this action, in and of itself, can be used as a fast bzero-type function. This hint is not implemented in the Release 6 architecture and generates a Reserved Instruction exception (RI).
31	Reserved.	Pre-Release 6: Unassigned by the Architecture — available for implementation-dependent use. This hint is not implemented in the Release 6 architecture and generates a Reserved Instruction exception (RI).

Restrictions:

None

This instruction does not produce an exception for a misaligned memory address, since it has no memory access size.

Availability and Compatibility:

This instruction has been reallocated an opcode in Release 6.

Operation:

```

vAddr ← GPR[base] + sign_extend(offset)
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, LOAD)
Prefetch(CCA, pAddr, vAddr, DATA, hint)

```

Exceptions:

Bus Error, Cache Error

Prefetch does not take any TLB-related or address-related exceptions under any circumstances.

Programming Notes:

In the Release 6 architecture, hint codes 2:3, 10:11, 18:19 behave as a NOP if not implemented. Hint codes 24:31 are not implemented (treated as reserved) and always signal a Reserved Instruction exception (RI).

As shown in the instruction drawing above, Release 6 implements a 9-bit offset, whereas all release levels lower than Release 6 of the MIPS architecture implement a 16-bit offset.

Prefetch cannot move data to or from a mapped location unless the translation for that location is present in the TLB. Locations in memory pages that have not been accessed recently may not have translations in the TLB, so prefetch may not be effective for such locations.

Prefetch does not cause addressing exceptions. A prefetch may be used using an address pointer before the validity of the pointer is determined without worrying about an addressing exception.

It is implementation dependent whether a Bus Error or Cache Error exception is reported if such an error is detected as a byproduct of the action taken by the PREF instruction. Typically, this only occurs in systems which have high-reliability requirements.

Prefetch operations have no effect on cache lines that were previously locked with the CACHE instruction.

Hint field encodings whose function is described as “streamed” or “retained” convey usage intent from software to hardware. Software should not assume that hardware will always prefetch data in an optimal way. If data is to be truly retained, software should use the Cache instruction to lock data into the cache.

Format: PREFE hint,offset(base)

MIPS32

Purpose: Prefetch EVA

To move data between user mode virtual address space memory and cache while operating in kernel mode.

Description: prefetch_memory(GPR[base] + offset)

PREFE adds the 9-bit signed *offset* to the contents of GPR *base* to form an effective byte address. The *hint* field supplies information about the way that the data is expected to be used.

PREFE enables the processor to take some action, causing data to be moved to or from the cache, to improve program performance. The action taken for a specific PREFE instruction is both system and context dependent. Any action, including doing nothing, is permitted as long as it does not change architecturally visible state or alter the meaning of a program. Implementations are expected either to do nothing, or to take an action that increases the performance of the program. The PrepareForStore function is unique in that it may modify the architecturally visible state.

PREFE does not cause addressing-related exceptions, including TLB exceptions. If the address specified would cause an addressing exception, the exception condition is ignored and no data movement occurs. However even if no data is moved, some action that is not architecturally visible, such as writeback of a dirty cache line, can take place.

It is implementation dependent whether a Bus Error or Cache Error exception is reported if such an error is detected as a byproduct of the action taken by the PREFE instruction.

PREFE neither generates a memory operation nor modifies the state of a cache line for a location with an *uncached* memory access type, whether this type is specified by the address segment (for example, kseg1), the programmed cacheability and coherency attribute of a segment (for example, the use of the *K0*, *KU*, or *K23* fields in the *Config* register), or the per-page cacheability and coherency attribute provided by the TLB.

If PREFE results in a memory operation, the memory access type and cacheability & coherency attribute used for the operation are determined by the memory access type and cacheability & coherency attribute of the effective address, just as it would be if the memory operation had been caused by a load or store to the effective address.

For a cached location, the expected and useful action for the processor is to prefetch a block of data that includes the effective address. The size of the block and the level of the memory hierarchy it is fetched into are implementation specific.

In coherent multiprocessor implementations, if the effective address uses a coherent Cacheability and Coherency Attribute (CCA), then the instruction causes a coherent memory transaction to occur. This means a prefetch issued on one processor can cause data to be evicted from the cache in another processor.

The PREFE instruction and the memory transactions which are sourced by the PREFE instruction, such as cache refill or cache writeback, obey the ordering and completion rules of the SYNC instruction.

The PREFE instruction functions in exactly the same fashion as the PREF instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to one.

Table 5.3 Values of *hint* Field for PREFE Instruction

Value	Name	Data Use and Desired Prefetch Action
0	load	Use: Prefetched data is expected to be read (not modified). Action: Fetch data as if for a load.
1	store	Use: Prefetched data is expected to be stored or modified. Action: Fetch data as if for a store.
2	Reserved Implementation Dependent	Reserved for future use - not available to implementations. Implementation dependent in Release 6. This hint code marks the line as LRU in the L1 cache and thus preferred for next eviction. Implementations can choose to writeback and/or invalidate as long as no architectural state is modified.
3	Reserved Implementation Dependent	Reserved for future use - not available to implementations. This hint code is unused In the Release 6 architecture.
4	load_streamed	Use: Prefetched data is expected to be read (not modified) but not reused extensively; it “streams” through cache. Action: Fetch data as if for a load and place it in the cache so that it does not displace data prefetched as “retained.”
5	store_streamed	Use: Prefetched data is expected to be stored or modified but not reused extensively; it “streams” through cache. Action: Fetch data as if for a store and place it in the cache so that it does not displace data prefetched as “retained.”
6	load_retained	Use: Prefetched data is expected to be read (not modified) and reused extensively; it should be “retained” in the cache. Action: Fetch data as if for a load and place it in the cache so that it is not displaced by data prefetched as “streamed.”
7	store_retained	Use: Prefetched data is expected to be stored or modified and reused extensively; it should be “retained” in the cache. Action: Fetch data as if for a store and place it in the cache so that it is not displaced by data prefetched as “streamed.”
8-15	Reserved	In the Release 6 architecture, hint codes 8 - 15 are treated the same as hint codes 0 - 7 respectively, but operate on the L2 cache.
16-23	Reserved	In the Release 6 architecture, hint codes 16 - 23 are treated the same as hint codes 0 - 7 respectively, but operate on the L3 cache.
8-20	Reserved	Reserved for future use - not available to implementations.
21-23	Implementation Dependent	Unassigned by the Architecture - available for implementation-dependent use.
24	Implementation Dependent Reserved in Release 6	Unassigned by the Architecture - available for implementation-dependent use. This hint code is not implemented in the Release 6 architecture and generates a Reserved Instruction exception (RI).

Table 5.3 Values of *hint* Field for PREFE Instruction

25	writeback_invalidate (also known as “nudge”) Reserved in Release 6	Use: Data is no longer expected to be used. Action: For a writeback cache, schedule a writeback of any dirty data. At the completion of the writeback, mark the state of any cache lines written back as invalid. If the cache line is not dirty, it is implementation dependent whether the state of the cache line is marked invalid or left unchanged. If the cache line is locked, no action is taken. This hint code is not implemented in the Release 6 architecture and generates a Reserved Instruction exception (RI).
26-29	Implementation Dependent Reserved in Release 6	Unassigned by the Architecture - available for implementation-dependent use. These hint codes are not implemented in the Release 6 architecture and generate a Reserved Instruction exception (RI).
30	PrepareForStore Reserved in Release 6	Use: Prepare the cache for writing an entire line, without the overhead involved in filling the line from memory. Action: If the reference hits in the cache, no action is taken. If the reference misses in the cache, a line is selected for replacement, any valid and dirty victim is written back to memory, the entire line is filled with zero data, and the state of the line is marked as valid and dirty. Programming Note: Because the cache line is filled with zero data on a cache miss, software must not assume that this action, in and of itself, can be used as a fast bzero-type function. This hint code is not implemented in the Release 6 architecture and generates a Reserved Instruction exception (RI).
31	Implementation Dependent Reserved in Release 6	Unassigned by the Architecture - available for implementation-dependent use. This hint code is not implemented in the Release 6 architecture and generates a Reserved Instruction exception (RI).

Restrictions:

Only usable when access to Coprocessor0 is enabled and when accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

This instruction does not produce an exception for a misaligned memory address, since it has no memory access size.

Operation:

```
vAddr ← GGPR[base] + sign_extend(offset)
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, LOAD)
Prefetch(CCA, pAddr, vAddr, DATA, hint)
```

Exceptions:

Bus Error, Cache Error, Address Error, Reserved Instruction, Coprocessor Usable

Prefetch does not take any TLB-related or address-related exceptions under any circumstances.

Programming Notes:

In the Release 6 architecture, hint codes 0:23 behave as a NOP and never signal a Reserved Instruction exception (RI). Hint codes 24:31 are not implemented (treated as reserved) and always signal a Reserved Instruction exception (RI).

Prefetch cannot move data to or from a mapped location unless the translation for that location is present in the TLB. Locations in memory pages that have not been accessed recently may not have translations in the TLB, so prefetch may not be effective for such locations.

Prefetch does not cause addressing exceptions. A prefetch may be used using an address pointer before the validity of the pointer is determined without worrying about an addressing exception.

It is implementation dependent whether a Bus Error or Cache Error exception is reported if such an error is detected as a byproduct of the action taken by the PREFE instruction. Typically, this only occurs in systems which have high-reliability requirements.

Prefetch operations have no effect on cache lines that were previously locked with the CACHE instruction.

Hint field encodings whose function is described as “streamed” or “retained” convey usage intent from software to hardware. Software should not assume that hardware will always prefetch data in an optimal way. If data is to be truly retained, software should use the Cache instruction to lock data into the cache.

31	26	25	21	20	16	15	11	10	6	5	0
COP1X 010011		base		index		hint		0 00000		PREFIX 001111	
6		5		5		5		5		6	

Format: PREFIX hint, index(base)

removed in Release 6
MIPS32 Release 2, removed in Release 6

Purpose: Prefetch Indexed

To move data between memory and cache.

Description: `prefetch_memory[GPR[base] + GPR[index]]`

PREFIX adds the contents of GPR *index* to the contents of GPR *base* to form an effective byte address. The *hint* field supplies information about the way the data is expected to be used.

The only functional difference between the PREF and PREFIX instructions is the addressing mode implemented by the two. Refer to the PREF instruction for all other details, including the encoding of the *hint* field.

Restrictions:

Availability and Compatibility:

Required in all versions of MIPS64 since MIPS64 Release 1. Not available in MIPS32 Release 1. Required by MIPS32 Release 2 and subsequent versions of MIPS32. When required, required whenever FPU is present, whether a 32-bit or 64-bit FPU, whether in 32-bit or 64-bit FP Register Mode ($FIR_{F64}=0$ or 1, $Status_{FR}=0$ or 1).

This instruction has been removed in Release 6.

Operation:

```
vAddr ← GPR[base] + GPR[index]
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, LOAD)
Prefetch(CCA, pAddr, vAddr, DATA, hint)
```

Exceptions:

Coprocessor Unusable, Reserved Instruction, Bus Error, Cache Error

Programming Notes:

The PREFIX instruction is only available on processors that implement floating point and should never be generated by compilers in situations other than those in which the corresponding load and store indexed floating point instructions are generated.

Refer to the corresponding section in the PREF instruction description.

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001			fmt 10110		ft		fs		fd		PUL 101110
6			5		5		5		5		6

Format: PUL.PS *fd*, *fs*, *ft*

MIPS32 Release 2, removed in Release 6

Purpose: Pair Upper Lower

To merge a pair of paired single values with realignment.

Description: $\text{FPR}[\text{fd}] \leftarrow \text{upper}(\text{FPR}[\text{fs}]) \mid \mid \text{lower}(\text{FPR}[\text{ft}])$

A new paired-single value is formed by catenating the upper single of FPR *fs* (bits **63..32**) and the lower single of FPR *ft* (bits **31..0**).

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *PS*. If the fields are not valid, the result is **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

$\text{StoreFPR}(\text{fd}, \text{PS}, \text{ValueFPR}(\text{fs}, \text{PS})_{63..32} \mid \mid \text{ValueFPR}(\text{ft}, \text{PS})_{31..0})$

Exceptions:

Coprocessor Unusable, Reserved Instruction

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001			fmt 10110		ft		fs		fd		PUU 101111
6			5		5		5		5		6

Format: PUU.PS *fd*, *fs*, *ft*

MIPS32 Release 2, removed in Release 6

Purpose: Pair Upper Upper

To merge a pair of paired single values with realignment.

Description: $\text{FPR}[\text{fd}] \leftarrow \text{upper}(\text{FPR}[\text{fs}]) \mid \mid \text{upper}(\text{FPR}[\text{ft}])$

A new paired-single value is formed by catenating the upper single of FPR *fs* (bits **63..32**) and the upper single of FPR *ft* (bits **63..32**).

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *PS*. If the fields are not valid, the result is **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

$\text{StoreFPR}(\text{fd}, \text{PS}, \text{ValueFPR}(\text{fs}, \text{PS})_{63..32} \mid \mid \text{ValueFPR}(\text{ft}, \text{PS})_{63..32})$

Exceptions:

Coprocessor Unusable, Reserved Instruction

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL3 0111 11	0 00 000	rt	rd		0 000 00					RDHWR 11 1011	
6	5	5	5		2	3				6	

Format: RDHWR *rt*, *rd*

MIPS32 Release 2

Purpose: Read Hardware Register

To move the contents of a hardware register to a general purpose register (GPR) if that operation is enabled by privileged software.

The purpose of this instruction is to give user mode access to specific information that is otherwise only visible in kernel mode.

Description: $GPR[rt] \leftarrow HWR[rd]$

If access is allowed to the specified hardware register, the contents of the register specified by *rd* is loaded into general register *rt*. Access control for each register is selected by the bits in the coprocessor 0 *HWREna* register.

The available hardware registers, and the encoding of the *rd* field for each, are shown in [Table 5.4](#).

Table 5.4 RDHWR Register Numbers

Register Number (<i>rd</i> Value)	Mnemonic	Description										
0	CPUNum	Number of the CPU on which the program is currently running. This register provides read access to the coprocessor 0 <i>EBase</i> _{CPUNum} field.										
1	SYNCL_Step	Address step size to be used with the SYNCL instruction, or zero if no caches need be synchronized. See that instruction’s description for the use of this value.										
2	CC	High-resolution cycle counter. This register provides read access to the coprocessor 0 <i>Count</i> Register.										
3	CCRes	Resolution of the CC register. This value denotes the number of cycles between update of the register. For example:										
		<table><tr><th>CCRes Value</th><th>Meaning</th></tr><tr><td>1</td><td>CC register increments every CPU cycle</td></tr><tr><td>2</td><td>CC register increments every second CPU cycle</td></tr><tr><td>3</td><td>CC register increments every third CPU cycle</td></tr><tr><td colspan="2">etc.</td></tr></table>	CCRes Value	Meaning	1	CC register increments every CPU cycle	2	CC register increments every second CPU cycle	3	CC register increments every third CPU cycle	etc.	
		CCRes Value	Meaning									
		1	CC register increments every CPU cycle									
		2	CC register increments every second CPU cycle									
3	CC register increments every third CPU cycle											
etc.												
4-28		These registers numbers are reserved for future architecture use. Access results in a Reserved Instruction Exception.										
29	ULR	User Local Register. This register provides read access to the coprocessor 0 <i>UserLocal</i> register, if it is implemented. In some operating environments, the <i>UserLocal</i> register is a pointer to a thread-specific storage block.										
30-31		These register numbers are reserved for implementation-dependent use. If they are not implemented, access results in a Reserved Instruction Exception.										

Restrictions:

In implementations of Release 1 of the Architecture, this instruction resulted in a Reserved Instruction Exception.

Access to the specified hardware register is enabled if Coprocessor 0 is enabled, or if the corresponding bit is set in the *HWREna* register. If access is not allowed or the register is not implemented, a Reserved Instruction Exception is signaled.

Operation:

```

case rd
    0: temp ← EBaseCPUNum
    1: temp ← SYNCI_StepSize()
    2: temp ← Count
    3: temp ← CountResolution()
    29: temp ← UserLocal
    30: temp ← Implementation-Dependent-Value
    31: temp ← Implementation-Dependent-Value
    otherwise: SignalException(ReservedInstruction)
endcase
GPR[rt] ← temp

```

Exceptions:

Reserved Instruction

31	26	25	21	20	16	15	11	10	0
COP0 0100 00			RDPGPR 01 010		rt		rd		0 000 0000 0000
6			5		5		5		11

Format: RDPGPR rd, rt

MIPS32 Release 2

Purpose: Read GPR from Previous Shadow Set

To move the contents of a GPR from the previous shadow set to a current GPR.

Description: $GPR[rd] \leftarrow SGPR[SRSCtl_{pss}, rt]$

The contents of the shadow GPR register specified by *SRSCtl_{pss}* (signifying the previous shadow set number) and *rt* (specifying the register number within that set) is moved to the current GPR *rd*.

Restrictions:

In implementations prior to Release 2 of the Architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

$GPR[rd] \leftarrow SGPR[SRSCtl_{pss}, rt]$

Exceptions:

Coprocessor Unusable

Reserved Instruction

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt		0 00000		fs		fd		RECIP 010101		
6	5		5		5		5		6		

Format: RECIP.fmt
 RECIP.S fd, fs
 RECIP.D fd, fs

MIPS32 Release 2
 MIPS32 Release 2

Purpose: Reciprocal Approximation

To approximate the reciprocal of an FP value (quickly).

Description: $FPR[fd] \leftarrow 1.0 / FPR[fs]$

The reciprocal of the value in FPR *fs* is approximated and placed into FPR *fd*. The operand and result are values in format *fmt*.

The numeric accuracy of this operation is implementation dependent. It does not meet the accuracy specified by the IEEE 754 Floating Point standard. The computed result differs from the both the exact result and the IEEE-mandated representation of the exact result by no more than one unit in the least-significant place (ULP).

It is implementation dependent whether the result is affected by the current rounding mode in *FCSR*.

Restrictions:

The fields *fs* and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Availability and Compatibility:

RECIP.S and RECIP.D: Required in all versions of MIPS64 since MIPS64 Release 1. Not available in MIPS32 Release 1. Required in MIPS32 Release 2 and all subsequent versions of MIPS32. When required, required whenever FPU is present, whether a 32-bit or 64-bit FPU, whether in 32-bit or 64-bit FP Register Mode ($FIR_{F64}=0$ or 1, $Status_{FR}=0$ or 1).

Operation:

`StoreFPR(fd, fmt, 1.0 / valueFPR(fs, fmt))`

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Division-by-zero, Unimplemented Op, Invalid Op, Overflow, Underflow

Format: RINT.fmt
 RINT.S fd, fs
 RINT.D fd, fs

MIPS32 Release 6
MIPS32 Release 6
MIPS32 Release 6

Purpose: Floating-Point Round to Integral

Scalar floating-point round to integral floating point value.

Description: $FPR[fd] \leftarrow \text{round_int}(FPR[fs])$

The scalar floating-point value in the register *fs* is rounded to an integral valued floating-point number in the same format based on the rounding mode bits *RM* in the FPU Control and Status Register *FCSR*. The result is written to *fd*.

The operands and results are values in floating-point data format *fmt*.

The RINT.fmt instruction corresponds to the **roundToIntegralExact** operation in the IEEE Standard for Floating-Point Arithmetic 754TM-2008. The Inexact exception is signaled if the result does not have the same numerical value as the input operand.

The floating point scalar instruction RINT.fmt corresponds to the MSA vector instruction FRINT.df. I.e. RINT.S corresponds to FRINT.W, and RINT.D corresponds to FRINT.D.

Restrictions:

Data-dependent exceptions are possible as specified by the IEEE Standard for Floating-Point Arithmetic 754TM-2008.

Availability and Compatibility:

This instruction is introduced by and required as of Release 6.

Operation:

RINT.fmt:

```

if not IsCoprorocessorEnabled(1)
  then SignalException(CoprorocessorUnusable, 1) end if
if not IsFloatingPointImplemented(fmt)
  then SignalException(ReservedInstruction) end if
if fmt=D and FIR.D=0
  then SignalFPEException(UnimplementedOperation) end if

fin ← ValueFPR(fs,fmt)
ftmp ← RoundIntFP(fin, fmt)
if ( fin ≠ ftmp ) SignalFPEException(InExact)
StoreFPR (fd, fmt, ftmp )

function RoundIntFP(tt, n)
  /* Round to integer operation, using rounding mode FCSR.RM*/
endfunction RoundIntFP
```

Exceptions:

Coprorocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation, Invalid Operation, Inexact, Overflow, Underflow

Format: ROTR *rd*, *rt*, *sa*

SmartMIPS Crypto, MIPS32 Release 2

Purpose: Rotate Word Right

To execute a logical right-rotate of a word by a fixed number of bits.

Description: $GPR[rd] \leftarrow GPR[rt] \times(right) sa$

The contents of the low-order 32-bit word of GPR *rt* are rotated right; the word result is placed in GPR *rd*. The bit-rotate amount is specified by *sa*.

Restrictions:

Operation:

```

if ((ArchitectureRevision() < 2) and (Config3SM = 0)) then
    UNPREDICTABLE
endif
s ← sa
temp ← GPR[rt]s-1..0 || GPR[rt]31..s
GPR[rd] ← temp

```

Exceptions:

Reserved Instruction

Format: ROTRV rd, rt, rs

SmartMIPS Crypto, MIPS32 Release 2

Purpose: Rotate Word Right Variable

To execute a logical right-rotate of a word by a variable number of bits.

Description: $GPR[rd] \leftarrow GPR[rt] \times(\text{right}) GPR[rs]$

The contents of the low-order 32-bit word of GPR *rt* are rotated right; the word result is placed in GPR *rd*. The bit-rotate amount is specified by the low-order 5 bits of GPR *rs*.

Restrictions:

Operation:

```

if ((ArchitectureRevision() < 2) and (Config3SM = 0)) then
    UNPREDICTABLE
endif
s ← GPR[rs]4..0
temp ← GPR[rt]s-1..0 || GPR[rt]31..s
GPR[rd] ← temp

```

Exceptions:

Reserved Instruction

6						5		5		5		5		6	

Format: ROUND.L.fmt

ROUND.L.S fd, fs

ROUND.L.D fd, fs

MIPS32 Release 2

MIPS32 Release 2

Purpose: Floating Point Round to Long Fixed Point

To convert an FP value to 64-bit fixed point, rounding to nearest.

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

The value in FPR *fs*, in format *fmt*, is converted to a value in 64-bit long fixed point format and rounded to nearest/even (rounding mode 0). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{63} to $2^{63}-1$, the result cannot be represented correctly and an IEEE Invalid Operation condition exists. The Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, $2^{63}-1$, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs: *fs* for type *fmt* and *fd* for long fixed point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. It is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Operation:

$\text{StoreFPR}(fd, L, \text{ConvertFmt}(\text{ValueFPR}(fs, fmt), fmt, L))$

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Unimplemented Operation, Invalid Operation

MIPS32

MIPS32

Purpose: Floating Point Round to Word Fixed Point

To convert an FP value to 32-bit fixed point, rounding to nearest.

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

The value in FPR *fs*, in format *fmt*, is converted to a value in 32-bit word fixed point format rounding to nearest/even (rounding mode 0). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{31} to $2^{31}-1$, the result cannot be represented correctly and an IEEE Invalid Operation condition exists. The Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, $2^{31}-1$, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs: *fs* for type *fmt* and *fd* for word fixed point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

`StoreFPR(fd, W, ConvertFmt(ValueFPR(fs, fmt), fmt, W))`

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Unimplemented Operation, Invalid Operation

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt		0 00000		fs		fd		RSQRT 010110		
6	5		5		5		5		6		

Format: RSQRT.fmt
 RSQRT.S fd, fs
 RSQRT.D fd, fs

MIPS32 Release 2
MIPS32 Release 2

Purpose: Reciprocal Square Root Approximation

To approximate the reciprocal of the square root of an FP value (quickly).

Description: $\text{FPR}[\text{fd}] \leftarrow 1.0 / \text{sqrt}(\text{FPR}[\text{fs}])$

The reciprocal of the positive square root of the value in FPR *fs* is approximated and placed into FPR *fd*. The operand and result are values in format *fmt*.

The numeric accuracy of this operation is implementation dependent; it does not meet the accuracy specified by the IEEE 754 Floating Point standard. The computed result differs from both the exact result and the IEEE-mandated representation of the exact result by no more than two units in the least-significant place (ULP).

The effect of the current *FCSR* rounding mode on the result is implementation dependent.

Restrictions:

The fields *fs* and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Availability and Compatibility:

RSQRT.S and RSQRT.D: Required in all versions of MIPS64 since MIPS64 Release 1. Not available in MIPS32 Release 1. Required in MIPS32 Release 2 and all subsequent versions of MIPS32. When required, required whenever FPU is present, whether a 32-bit or 64-bit FPU, whether in 32-bit or 64-bit FP Register Mode ($\text{FIR}_{F64}=0$ or 1, $\text{Status}_{FR}=0$ or 1).

Operation:

$\text{StoreFPR}(\text{fd}, \text{fmt}, 1.0 / \text{SquareRoot}(\text{valueFPR}(\text{fs}, \text{fmt})))$

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Division-by-zero, Unimplemented Operation, Invalid Operation, Overflow, Underflow

Format: SB *rt*, *offset*(*base*)

MIPS32

Purpose: Store Byte

To store a byte to memory.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{GPR}[\text{rt}]$

The least-significant 8-bit byte of GPR *rt* is stored in memory at the location specified by the effective address. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

None

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
pAddr ← pAddrPSIZE-1..2 || (pAddr1..0 xor ReverseEndian2)
bytesel ← vAddr1..0 xor BigEndianCPU2
dataword ← GPR[rt]31-8*bytesel..0 || 08*bytesel
StoreMemory (CCA, BYTE, dataword, pAddr, vAddr, DATA)

```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Bus Error, Address Error, Watch

Format: SBE *rt*, *offset*(*base*)

MIPS32

Purpose: Store Byte EVA

To store a byte to user mode virtual address space when executing in kernel mode.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{GPR}[\text{rt}]$

The least-significant 8-bit byte of GPR *rt* is stored in memory at the location specified by the effective address. The 9-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

The SBE instruction functions the same as the SB instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to 1.

Restrictions:

Only usable when access to Coprocessor0 is enabled and when accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
pAddr ← pAddrPSIZE-1..2 || (pAddr1..0 xor ReverseEndian2)
bytesel ← vAddr1..0 xor BigEndianCPU2
dataword ← GPR[rt]31-8*bytesel..0 || 08*bytesel
StoreMemory (CCA, BYTE, dataword, pAddr, vAddr, DATA)

```

Exceptions:

TLB Refill

TLB Invalid

Bus Error

Address Error

Watch

Reserved Instruction

Coprocessor Unusable

pre-Release 6

Release 6

**Format:** SC *rt*, *offset*(*base*)**MIPS32****Purpose:** Store Conditional Word

To store a word to memory to complete an atomic read-modify-write

Description: if `atomic_update` then `memory[GPR[base] + offset] ← GPR[rt]`, `GPR[rt] ← 1`
 else `GPR[rt] ← 0`

The LL and SC instructions provide primitives to implement atomic read-modify-write (RMW) operations on synchronizable memory locations. In Release 5, the behavior of SC is modified when *Config5_{LLB}*=1.

The 32-bit word in GPR *rt* is conditionally stored in memory at the location specified by the aligned effective address. The signed *offset* is added to the contents of GPR *base* to form an effective address.

The SC completes the RMW sequence begun by the preceding LL instruction executed on the processor. To complete the RMW sequence atomically, the following occur:

- The 32-bit word of GPR *rt* is stored to memory at the location specified by the aligned effective address.
- A one, indicating success, is written into GPR *rt*.

Otherwise, memory is not modified and a 0, indicating failure, is written into GPR *rt*.

If either of the following events occurs between the execution of LL and SC, the SC fails:

- A coherent store is completed by another processor or coherent I/O module into the block of synchronizable physical memory containing the word. The size and alignment of the block is implementation-dependent, but it is at least one word and at most the minimum page size.
- A coherent store is executed between an LL and SC sequence on the same processor to the block of synchronizable physical memory containing the word (if *Config5_{LLB}*=1; else whether such a store causes the SC to fail is not predictable).
- An ERET instruction is executed. (Release 5 includes ERETNC, which will not cause the SC to fail.)

Furthermore, an SC must always compare its address against that of the LL. An SC will fail if the aligned address of the SC does not match that of the preceding LL.

A load that executes on the processor executing the LL/SC sequence to the block of synchronizable physical memory containing the word, will not cause the SC to fail (if *Config5_{LLB}*=1; else such a load may cause the SC to fail).

If any of the events listed below occurs between the execution of LL and SC, the SC may fail where it could have suc-

ceeded, i.e., success is not predictable. Portable programs should not cause any of these events.

- A load or store executed on the processor executing the LL and SC that is not to the block of synchronizable physical memory containing the word. (The load or store may cause a cache eviction between the LL and SC that results in SC failure. The load or store does not necessarily have to occur between the LL and SC.)
- Any prefetch that is executed on the processor executing the LL and SC sequence (due to a cache eviction between the LL and SC).
- A non-coherent store executed between an LL and SC sequence to the block of synchronizable physical memory containing the word.
- The instructions executed starting with the LL and ending with the SC do not lie in a 2048-byte contiguous region of virtual memory. (The region does not have to be aligned, other than the alignment required for instruction words.)

CACHE operations that are local to the processor executing the LL/SC sequence will result in unpredictable behaviour of the SC if executed between the LL and SC, that is, they may cause the SC to fail where it could have succeeded. Non-local CACHE operations (address-type with coherent CCA) may cause an SC to fail on either the local processor or on the remote processor in multiprocessor or multi-threaded systems. This definition of the effects of CACHE operations is mandated if *Config5_{LLB}*=1. If *Config5_{LLB}*=0, then CACHE effects are implementation-dependent.

The following conditions must be true or the result of the SC is not predictable—the SC may fail or succeed (if *Config5_{LLB}*=1, then either success or failure is mandated, else the result is **UNPREDICTABLE**):

- Execution of SC must have been preceded by execution of an LL instruction.
- An RMW sequence executed without intervening events that would cause the SC to fail must use the same address in the LL and SC. The address is the *same* if the virtual address, physical address, and cacheability & coherency attribute are identical.

Atomic RMW is provided only for synchronizable memory locations. A synchronizable memory location is one that is associated with the state and logic necessary to implement the LL/SC semantics. Whether a memory location is synchronizable depends on the processor and system configurations, and on the memory access type used for the location:

- **Uniprocessor atomicity:** To provide atomic RMW on a single processor, all accesses to the location must be made with memory access type of either *cached noncoherent* or *cached coherent*. All accesses must be to one or the other access type, and they may not be mixed.
- **MP atomicity:** To provide atomic RMW among multiple processors, all accesses to the location must be made with a memory access type of *cached coherent*.
- **I/O System:** To provide atomic RMW with a coherent I/O system, all accesses to the location must be made with a memory access type of *cached coherent*. If the I/O system does not use coherent memory operations, then atomic RMW cannot be provided with respect to the I/O reads and writes.

Restrictions:

The addressed location must have a memory access type of *cached noncoherent* or *cached coherent*; if it does not, the result is **UNPREDICTABLE**.

The effective address must be naturally-aligned. If either of the 2 least-significant bits of the address is non-zero, an

Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions such as LW (Load Word). However, this instruction is a special memory reference instruction for which misaligned support is NOT provided, and for which signalling an exception (AddressError) on a misaligned access is required.

Availability and Compatibility:

This instruction has been reallocated an opcode in Release 6.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
if vAddr1..0 ≠ 02 then
    SignalException(AddressError)
endif
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
dataword ← GPR[rt]
if LLbit then
    StoreMemory (CCA, WORD, dataword, pAddr, vAddr, DATA)
endif
GPR[rt] ← 031 || LLbit
LLbit ← 0 // if Config5LLB=1, SC always clears LLbit regardless of address match.

```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Address Error, Watch

Programming Notes:

LL and SC are used to atomically update memory locations, as shown below.

```

L1:
    LL      T1, (T0)  # load counter
    ADDI    T2, T1, 1 # increment
    SC      T2, (T0)  # try to store, checking for atomicity
    BEQ     T2, 0, L1 # if not atomic (0), try again
    NOP                                # branch-delay slot

```

Exceptions between the LL and SC cause SC to fail, so persistent exceptions must be avoided. Some examples of these are arithmetic operations that trap, system calls, and floating point operations that trap or require software emulation assistance.

LL and SC function on a single processor for *cached noncoherent* memory so that parallel programs can be run on uniprocessor systems that do not support *cached coherent* memory access types.

As shown in the instruction drawing above, Release 6 implements a 9-bit offset, whereas all release levels lower than Release 6 of the MIPS architecture implement a 16-bit offset.

Format: SCE *rt*, *offset*(*base*)

MIPS32

Purpose: Store Conditional Word EVA

To store a word to user mode virtual memory while operating in kernel mode to complete an atomic read-modify-write.

Description: if `atomic_update` then `memory[GPR[base] + offset] ← GPR[rt]`, `GPR[rt] ← 1` else `GPR[rt] ← 0`

The LL and SC instructions provide primitives to implement atomic read-modify-write (RMW) operations for synchronizable memory locations.

The 32-bit word in GPR *rt* is conditionally stored in memory at the location specified by the aligned effective address. The 9-bit signed *offset* is added to the contents of GPR *base* to form an effective address.

The SCE completes the RMW sequence begun by the preceding LLE instruction executed on the processor. To complete the RMW sequence atomically, the following occurs:

- The 32-bit word of GPR *rt* is stored to memory at the location specified by the aligned effective address.
- A 1, indicating success, is written into GPR *rt*.

Otherwise, memory is not modified and a 0, indicating failure, is written into GPR *rt*.

If either of the following events occurs between the execution of LL and SC, the SC fails:

- A coherent store is completed by another processor or coherent I/O module into the block of synchronizable physical memory containing the word. The size and alignment of the block is implementation dependent, but it is at least one word and at most the minimum page size.
- An ERET instruction is executed.

If either of the following events occurs between the execution of LLE and SCE, the SCE may succeed or it may fail; the success or failure is not predictable. Portable programs should not cause one of these events.

- A memory access instruction (load, store, or prefetch) is executed on the processor executing the LLE/SCE.
- The instructions executed starting with the LLE and ending with the SCE do not lie in a 2048-byte contiguous region of virtual memory. (The region does not have to be aligned, other than the alignment required for instruction words.)

The following conditions must be true or the result of the SCE is **UNPREDICTABLE**:

- Execution of SCE must have been preceded by execution of an LLE instruction.
- An RMW sequence executed without intervening events that would cause the SCE to fail must use the same address in the LLE and SCE. The address is the same if the virtual address, physical address, and cacheability & coherency attribute are identical.

Atomic RMW is provided only for synchronizable memory locations. A synchronizable memory location is one that is associated with the state and logic necessary to implement the LLE/SCE semantics. Whether a memory location is

synchronizable depends on the processor and system configurations, and on the memory access type used for the location:

- **Uniprocessor atomicity:** To provide atomic RMW on a single processor, all accesses to the location must be made with memory access type of either *cached non coherent* or *cached coherent*. All accesses must be to one or the other access type, and they may not be mixed.
- **MP atomicity:** To provide atomic RMW among multiple processors, all accesses to the location must be made with a memory access type of *cached coherent*.
- **I/O System:** To provide atomic RMW with a coherent I/O system, all accesses to the location must be made with a memory access type of *cached coherent*. If the I/O system does not use coherent memory operations, then atomic RMW cannot be provided with respect to the I/O reads and writes.

The SCE instruction functions the same as the SC instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to 1.

Restrictions:

The addressed location must have a memory access type of *cached non coherent* or *cached coherent*; if it does not, the result is **UNPREDICTABLE**.

The effective address must be naturally-aligned. If either of the 2 least-significant bits of the address is non-zero, an Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions such as LW (Load Word). However, this instruction is a special memory reference instruction for which misaligned support is NOT provided, and for which signalling an exception (AddressError) on a misaligned access is required.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
if vAddr1..0 ≠ 02 then
    SignalException(AddressError)
endif
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
dataword ← GPR[rt]
if LLbit then
    StoreMemory (CCA, WORD, dataword, pAddr, vAddr, DATA)
endif
GPR[rt] ← 031 || LLbit

```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Address Error, Watch, Reserved Instruction, Coprocessor Unusable

Programming Notes:

LLE and SCE are used to atomically update memory locations, as shown below.

```

L1:
    LLE    T1, (T0)    # load counter

```

```
ADDI    T2, T1, 1 # increment
SCE     T2, (T0) # try to store, checking for atomicity
BEQ     T2, 0, L1 # if not atomic (0), try again
NOP                     # branch-delay slot
```

Exceptions between the LLE and SCE cause SCE to fail, so persistent exceptions must be avoided. Examples are arithmetic operations that trap, system calls, and floating point operations that trap or require software emulation assistance.

LLE and SCE function on a single processor for *cached non coherent* memory so that parallel programs can be run on uniprocessor systems that do not support *cached coherent* memory access types.

pre-Release 6

31	26	25	6	5	0
SPECIAL2 011100	code - use syscall				SDBBP 111111
6	20				6

Release 6

31	26	25	6	5	0
SPECIAL 000000	code - use syscall				SDBBP 001110
6	20				6

Format: SDBBP code**EJTAG****Purpose:** Software Debug Breakpoint

To cause a debug breakpoint exception

Description:

This instruction causes a debug exception, passing control to the debug exception handler. If the processor is executing in Debug Mode when the SDBBP instruction is executed, the exception is a Debug Mode Exception, which sets the Debug_{DExcCode} field to the value 0x9 (Bp). The code field can be used for passing information to the debug exception handler, and is retrieved by the debug exception handler only by loading the contents of the memory word containing the instruction, using the DEPC register. The CODE field is not used in any way by the hardware.

Restrictions:**Availability and Compatibility:**

This instruction has been reallocated an opcode in Release 6.

Operation:

```

NOP-ability for SDBBP. Also, signal hardware with ID
if Config5.SBRI=1 then /* SBRI is a MIPS Release 6 feature */
    SignalException(ReservedInstruction) endif
If DebugDM = 1 then SignalDebugModeBreakpointException() endif // nested
SignalDebugBreakpointException() // normal

```

Exceptions:

Debug Breakpoint Exception
 Debug Mode Breakpoint Exception

Programming Notes:

Release 6 changes the instruction encoding. The primary opcode changes from SPECIAL2 to SPECIAL. Also it defines a different function field value for SDBBP.

Format: SDC1 ft, offset(base)

MIPS32

Purpose: Store Doubleword from Floating Point

To store a doubleword from an FPR to memory.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{FPR}[\text{ft}]$

The 64-bit doubleword in FPR *ft* is stored in memory at the location specified by the aligned effective address. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

Pre-Release 6: An Address Error exception occurs if $\text{EffectiveAddress}_{2..0} \neq 0$ (not doubleword-aligned).

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses”](#) on page 511.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, STORE)
datadoubleword ← ValueFPR(ft, UNINTERPRETED_DOUBLEWORD)
paddr ← paddr xor ((BigEndianCPU xor ReverseEndian) || 02)
StoreMemory(CCA, WORD, datadoubleword31..0, pAddr, vAddr, DATA)
paddr ← paddr xor 0b100
StoreMemory(CCA, WORD, datadoubleword63..32, pAddr, vAddr+4, DATA)

```

Exceptions:

Coprocessor Unusable, Reserved Instruction, TLB Refill, TLB Invalid, TLB Modified, Address Error, Watch

pre-Release 6

Release 6

**Format:** SDC2 rt, offset(base)**MIPS32****Purpose:** Store Doubleword from Coprocessor 2

To store a doubleword from a Coprocessor 2 register to memory

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{CPR}[2, \text{rt}, 0]$

The 64-bit doubleword in Coprocessor 2 register *rt* is stored in memory at the location specified by the aligned effective address. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

Pre-Release 6: An Address Error exception occurs if $\text{EffectiveAddress}_{2..0} \neq 0$ (not doubleword-aligned).

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses” on page 511](#).

Availability and Compatibility:

This instruction has been reallocated an opcode in Release 6.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, STORE)
lsw ← CPR[2, rt, 0]
msw ← CPR[2, rt+1, 0]
paddr ← paddr xor ((BigEndianCPU xor ReverseEndian) || 02)
StoreMemory(CCA, WORD, lsw, pAddr, vAddr, DATA)
paddr ← paddr xor 0b100
StoreMemory(CCA, WORD, msw, pAddr, vAddr+4, DATA)

```

Exceptions:

Coprocessor Unusable, Reserved Instruction, TLB Refill, TLB Invalid, TLB Modified, Address Error, Watch

Programming Notes:

As shown in the instruction drawing above, Release 6 implements an 11-bit offset, whereas all release levels lower

than Release 6 of the MIPS architecture implement a 16-bit offset.

31	26	25	21	20	16	15	11	10	6	5	0
COP1X 010011		base		index		fs		0 00000		SDXC1 001001	
6		5		5		5		5		6	

Format: SDXC1 fs, index(base)

removed in Release 6
MIPS32 Release 2, removed in Release 6

Purpose: Store Doubleword Indexed from Floating Point

To store a doubleword from an FPR to memory (GPR+GPR addressing).

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{GPR}[\text{index}]] \leftarrow \text{FPR}[\text{fs}]$

The 64-bit doubleword in FPR *fs* is stored in memory at the location specified by the aligned effective address. The contents of GPR *index* and GPR *base* are added to form the effective address.

Restrictions:

An Address Error exception occurs if $\text{EffectiveAddress}_{2..0} \neq 0$ (not doubleword-aligned).

Availability and Compatibility:

This instruction has been removed in Release 6.

Required in all versions of MIPS64 since MIPS64 Release 1. Not available in MIPS32 Release 1. Required in MIPS32 Release 2 and all subsequent versions of MIPS32. When required, these instructions are to be implemented if an FPU is present either in a 32-bit or 64-bit FPU or in a 32-bit or 64-bit FP Register Mode ($\text{FIR}_{F64}=0$ or 1, $\text{Status}_{FR}=0$ or 1).

Operation:

```

vAddr ← GPR[base] + GPR[index]
if vAddr2..0 ≠ 03 then
    SignalException(AddressError)
endif
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, STORE)
datadoubleword ← ValueFPR(fs, UNINTERPRETED_DOUBLEWORD)
paddr ← paddr xor ((BigEndianCPU xor ReverseEndian) || 02)
StoreMemory(CCA, WORD, datadoubleword31..0, pAddr, vAddr, DATA)
paddr ← paddr xor 0b100
StoreMemory(CCA, WORD, datadoubleword63..32, pAddr, vAddr+4, DATA)

```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Coprocessor Unusable, Address Error, Reserved Instruction, Watch.

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL3 011111		0 00000		rt		rd		SEB 10000		BSHFL 100000	
6		5		5		5		5		6	

Format: SEB rd, rt

MIPS32 Release 2

Purpose: Sign-Extend Byte

To sign-extend the least significant byte of GPR *rt* and store the value into GPR *rd*.

Description: $\text{GPR}[\text{rd}] \leftarrow \text{SignExtend}(\text{GPR}[\text{rt}]_{7..0})$

The least significant byte from GPR *rt* is sign-extended and stored in GPR *rd*.

Restrictions:

Prior to architecture Release 2, this instruction resulted in a Reserved Instruction Exception.

Operation:

$\text{GPR}[\text{rd}] \leftarrow \text{sign_extend}(\text{GPR}[\text{rt}]_{7..0})$

Exceptions:

Reserved Instruction

Programming Notes:

For symmetry with the SEB and SEH instructions, you expect that there would be ZEB and ZEH instructions that zero-extend the source operand and expect that the SEW and ZEW instructions would exist to sign- or zero-extend a word to a doubleword. These instructions do not exist because there are functionally-equivalent instructions already in the instruction set. The following table shows the instructions providing the equivalent functions.

Expected Instruction	Function	Equivalent Instruction
ZEB rx, ry	Zero-Extend Byte	ANDI rx, ry, 0xFF
ZEH rx, ry	Zero-Extend Halfword	ANDI rx, ry, 0xFFFF

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL3 011111			0 00000		rt		rd		SEH 11000		BSHFL 100000
6			5		5		5		5		6

Format: SEH rd, rt

MIPS32 Release 2

Purpose: Sign-Extend Halfword

To sign-extend the least significant halfword of GPR *rt* and store the value into GPR *rd*.

Description: $\text{GPR}[\text{rd}] \leftarrow \text{SignExtend}(\text{GPR}[\text{rt}]_{15..0})$

The least significant halfword from GPR *rt* is sign-extended and stored in GPR *rd*.

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

$\text{GPR}[\text{rd}] \leftarrow \text{sign_extend}(\text{GPR}[\text{rt}]_{15..0})$

Exceptions:

Reserved Instruction

Programming Notes:

The SEH instruction can be used to convert two contiguous halfwords to sign-extended word values in three instructions. For example:

```
lw    t0, 0(a1)           /* Read two contiguous halfwords */
seh   t1, t0              /* t1 = lower halfword sign-extended to word */
sra   t0, t0, 16          /* t0 = upper halfword sign-extended to word */
```

Zero-extended halfwords can be created by changing the SEH and SRA instructions to ANDI and SRL instructions, respectively.

For symmetry with the SEB and SEH instructions, you expect that there would be ZEB and ZEH instructions that zero-extend the source operand and expect that the SEW and ZEW instructions would exist to sign- or zero-extend a word to a doubleword. These instructions do not exist because there are functionally-equivalent instructions already in the instruction set. The following table shows the instructions providing the equivalent functions.

Expected Instruction	Function	Equivalent Instruction
ZEB rx, ry	Zero-Extend Byte	ANDI rx, ry, 0xFF
ZEH rx, ry	Zero-Extend Halfword	ANDI rx, ry, 0xFFFF

Format: SEL.fmt
 SEL.S fd, fs, ft
 SEL.D fd, fs, ft

MIPS32 Release 6
MIPS32 Release 6

Purpose: Select floating point values with FPR condition

Description: $FPR[fd] \leftarrow FPR[fd].bit0 ? FPR[ft] : FPR[fs]$

SEL.fmt is a select operation, with a condition input in FPR fd, and 2 data inputs in FPRs ft and fs.

- If the condition is true, the value of ft is written to fd.
- If the condition is false, the value of fs is written to fd.

The condition input is specified by FPR fd, and is overwritten by the result.

The condition is true only if bit 0 of the condition input FPR fd is set. Other bits are ignored.

This instruction has floating point formats S and D, but these specify only the width of the operands. SEL.S can be used for 32-bit W data, and SEL.D can be used for 64 bit L data.

This instruction has no exception behavior. It does not trap on NaNs. It does not set the FPU Cause bits.

Restrictions:

None

Availability and Compatibility:

SEL.fmt is introduced by and required as of MIPS32 Release 6.

Special Considerations:

Only formats S and D are valid. Other format values may be used to encode other instructions. Unused format encodings are required to signal the Reserved Instruction exception.

Operation:

```
tmp ← ValueFPR(fd, UNINTERPRETED_WORD)
cond ← tmp.bit0
if cond then
    tmp ← ValueFPR(ft, fmt)
else
    tmp ← ValueFPR(fs, fmt)
endif
StoreFPR(fd, fmt, tmp)
```

Format: SELEQZ SELNEZ
 SELEQZ rd,rs,rt
 SELNEZ rd,rs,rt

MIPS32 Release 6
 MIPS32 Release 6

Purpose: Select integer GPR value or zero

Description:

SELEQZ: $GPR[rd] \leftarrow GPR[rd] := GPR[rt]=0 ? 0 : GPR[rs]$
 SELNEZ: $GPR[rd] \leftarrow GPR[rt] \neq 0 ? GPR[rs] : 0$

- SELEQZ is a select operation, with a condition input in GPR *rt*, one explicit data input in GPR *rs*, and implicit data input 0. The condition is true only if all bits in GPR *rt* are zero.
- SELNEZ is a select operation, with a condition input in GPR *rt*, one explicit data input in GPR *rs*, and implicit data input 0. The condition is true only if any bit in GPR *rt* is nonzero

If the condition is true, the value of *rs* is written to *rd*.

If the condition is false, the zero is written to *rd*.

This instruction operates on all GPRLEN bits of the CPU registers, that is, all 32 bits on a 32-bit CPU, and all 64 bits on a 64-bit CPU. All GPRLEN bits of *rt* are tested.

Restrictions:

None

Availability and Compatibility:

These instructions are introduced by and required as of MIPS32 Release 6.

Special Considerations:

None

Operation:

```
SELNEZ: cond ← GPR[rt] ≠ 0
SELEQZ: cond ← GPR[rt] = 0
if cond then
    result ← GPR[rs]
else
    result ← 0
endif
GPR[rd] ← result
```

Exceptions:

None

Programming Note:

Release 6 removes the Pre-Release 6 instructions MOVZ and MOVN:

```
MOVZ: if GPR[rt] = 0 then GPR[rd] ← GPR[rs]
MOVN: if GPR[rt] ≠ 0 then GPR[rd] ← GPR[rs]
```

MOVZ can be emulated using Release 6 instructions as follows:

```
SELEQZ at, rs, rt
SELNEZ rd, rd, rt
OR rd, rd, at
```

Similarly MOVN:

```
SELNEZ at, rs, rt
SELEQZ rd, rd, rt
OR rd, rd, at
```

The more general select operation requires 4 registers (1 output + 3 inputs (1 condition + 2 data)) and can be expressed:

```
rD ← if rC then rA else rB
```

The more general select can be created using Release 6 instructions as follows:

```
SELNEZ at, rB, rC
SELNEZ rD, rA, rC
OR rD, rD, at
```

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt S, D only		ft		fs		fd		SELEQZ 010100		
COP1 010001	fmt S, D only		ft		fs		fd		SELNEZ 010111		
6	5		5		5		5		6		

Format: SELEQZ.fmt SELNEQZ.fmt
 SELEQZ.S fd, fs, ft
 SELEQZ.D fd, fs, ft
 SELNEZ.S fd, fs, ft
 SELNEZ.D fd, fs, ft

MIPS32 Release 6
 MIPS32 Release 6
 MIPS32 Release 6
 MIPS32 Release 6

Purpose: Select floating point value or zero with FPR condition.

Description:

```
SELEQZ.fmt: FPR[fd] ← FPR[ft].bit0 ? 0 : FPR[fs]
SELNEZ.fmt: FPR[fd] ← FPR[ft].bit0 ? FPR[fs] : 0
```

- SELEQZ.fmt is a select operation, with a condition input in FPR ft, one explicit data input in FPR fs, and implicit data input 0. The condition is true only if bit 0 of FPR ft is zero.
- SELNEZ.fmt is a select operation, with a condition input in FPR ft, one explicit data input in FPR fs, and implicit data input 0. The condition is true only if bit 0 of FPR ft is nonzero.

If the condition is true, the value of fs is written to fd.

If the condition is false, the value that has all bits zero is written to fd.

This instruction has floating point formats S and D, but these specify only the width of the operands. Format S can be used for 32-bit W data, and format D can be used for 64 bit L data. The condition test is restricted to bit 0 of FPR ft. Other bits are ignored.

This instruction has no execution exception behavior. It does not trap on NaNs. It does not set the FPU Cause bits.

Restrictions:

FPR fd destination register bits beyond the format width are UNPREDICTABLE. For example, if fmt is S, then fd bits 0-31 are defined, but bits 32 and above are UNPREDICTABLE. For example, if fmt is D, then fd bits 0-63 are defined.

Availability and Compatibility:

These instructions are introduced by and required as of MIPS32 Release 6.

Special Considerations:

Only formats S and D are valid. Other format values may be used to encode other instructions. Unused format encodings are required to signal the Reserved Instruction exception.

Operation

```
tmp ← ValueFPR(ft, UNINTERPRETED_WORD)
SELEQZ: cond ← tmp.bit0 = 0
SELNEZ: cond ← tmp.bit0 ≠ 0
if cond then
    tmp ← ValueFPR(fs, fmt)
else
    tmp ← 0 /* all bits set to zero */
endif
StoreFPR(fd, fmt, tmp)
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Format: SH *rt*, *offset* (*base*)

MIPS32

Purpose: Store Halfword

To store a halfword to memory.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{GPR}[\text{rt}]$

The least-significant 16-bit halfword of register *rt* is stored in memory at the location specified by the aligned effective address. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

Pre-release 6: The effective address must be naturally-aligned. If the least-significant bit of the address is non-zero, an Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses” on page 511](#).

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
pAddr ← pAddr_PSIZE-1..2 || (pAddr_1..0 xor (ReverseEndian || 0))
bytesel ← vAddr_1..0 xor (BigEndianCPU || 0)
dataword ← GPR[rt]_31-8*bytesel..0 || 08*bytesel
StoreMemory (CCA, HALFWORD, dataword, pAddr, vAddr, DATA)

```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Address Error, Watch

Format: SHE *rt*, *offset*(*base*)

MIPS32

Purpose: Store Halfword EVA

To store a halfword to user mode virtual address space when executing in kernel mode.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{GPR}[\text{rt}]$

The least-significant 16-bit halfword of register *rt* is stored in memory at the location specified by the aligned effective address. The 9-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

The SHE instruction functions the same as the SH instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to 1.

Restrictions:

Only usable in kernel mode when accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

Pre-Release 6: The effective address must be naturally-aligned. If the least-significant bit of the address is non-zero, an Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses” on page 511](#).

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
pAddr ← pAddr_PSIZE-1..2 || (pAddr_1..0 xor (ReverseEndian || 0))
bytesel ← vAddr_1..0 xor (BigEndianCPU || 0)
dataword ← GPR[rt]_31-8*bytesel..0 || 08*bytesel
StoreMemory (CCA, HALFWORD, dataword, pAddr, vAddr, DATA)

```

Exceptions:

TLB Refill

TLB Invalid

Bus Error

Address Error

Watch

Reserved Instruction

Coprocessor Unusable

Format: SIGRIE code

MIPS32 Release 6

Purpose: Signal Reserved Instruction Exception

The SIGRIE instruction signals a Reserved Instruction Exception.

Description: `SignalException(ReservedInstruction)`

The SIGRIE instruction signals a Reserved Instruction Exception. Implementations should use exactly the same mechanisms as they use for reserved instructions that are not defined by the Architecture.

The 16-bit *code* field is available for software use.

Restrictions:

The 16-bit *code* field is available for software use. The value zero in the *code* field should never be overloaded for any other purpose. Software may provide extended functionality by interpreting nonzero values of the *code* field in a manner that is outside the scope of this architecture specification.

Availability and Compatibility:

This instruction is introduced by and required as of Release 6.

Pre-Release 6: this instruction encoding was reserved, and required to signal a Reserved Instruction exception. Therefore this instruction can be considered to be both backwards and forwards compatible.

The *rs* field of the SIGRIE instruction, bits 21-25, is required to be zero such as, 000001 . 00000 . 10011 . code.

Operation:

`SignalException(ReservedInstruction)`

Exceptions:

Reserved Instruction

31	26	25	21	20	16	15	11	10	6	5	0

Format: SLL rd, rt, sa

MIPS32

Purpose: Shift Word Left Logical

To left-shift a word by a fixed number of bits.

Description: $\text{GPR}[\text{rd}] \leftarrow \text{GPR}[\text{rt}] \ll \text{sa}$

The contents of the low-order 32-bit word of GPR *rt* are shifted left, inserting zeros into the emptied bits. The word result is placed in GPR *rd*. The bit-shift amount is specified by *sa*.

Restrictions:

None

Operation:

```

s ← sa
temp ← GPR[rt] (31-s) .. 0 || 0s
GPR[rd] ← temp

```

Exceptions:

None

Programming Notes:

SLL r0, r0, 0, expressed as NOP, is the assembly idiom used to denote no operation.

SLL r0, r0, 1, expressed as SSNOP, is the assembly idiom used to denote no operation that causes an issue break on superscalar processors.

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL 000000		rs		rt		rd		0 00000		SLLV 000100	
6		5		5		5		5		6	

Format: SLLV rd, rt, rs

MIPS32

Purpose: Shift Word Left Logical Variable

To left-shift a word by a variable number of bits.

Description: $\text{GPR}[\text{rd}] \leftarrow \text{GPR}[\text{rt}] \ll \text{GPR}[\text{rs}]$

The contents of the low-order 32-bit word of GPR *rt* are shifted left, inserting zeros into the emptied bits. The resulting word is placed in GPR *rd*. The bit-shift amount is specified by the low-order 5 bits of GPR *rs*.

Restrictions:

None

Operation:

```

s ← GPR[rs]4..0
temp ← GPR[rt](31-s)..0 || 0s
GPR[rd] ← temp

```

Exceptions:

None

Programming Notes:

None

31	26	25	21	20	16	15	11	10	6	5	0									
SPECIAL 000000						rs			rt			rd			0 00000			SLT 101010		
6						5			5			5			5			6		

Format: SLT rd, rs, rt

MIPS32

Purpose: Set on Less Than

To record the result of a less-than comparison.

Description: $\text{GPR}[\text{rd}] \leftarrow (\text{GPR}[\text{rs}] < \text{GPR}[\text{rt}])$

Compare the contents of GPR *rs* and GPR *rt* as signed integers; record the Boolean result of the comparison in GPR *rd*. If GPR *rs* is less than GPR *rt*, the result is 1 (true); otherwise, it is 0 (false).

The arithmetic comparison does not cause an Integer Overflow exception.

Restrictions:

None

Operation:

```

if GPR[rs] < GPR[rt] then
    GPR[rd] ← 0GPRLEN-1 || 1
else
    GPR[rd] ← 0GPRLEN
endif

```

Exceptions:

None

Format: SLTI *rt*, *rs*, *immediate*

MIPS32

Purpose: Set on Less Than Immediate

To record the result of a less-than comparison with a constant.

Description: $\text{GPR}[\text{rt}] \leftarrow (\text{GPR}[\text{rs}] < \text{immediate})$

Compare the contents of GPR *rs* and the 16-bit signed *immediate* as signed integers; record the Boolean result of the comparison in GPR *rt*. If GPR *rs* is less than *immediate*, the result is 1 (true); otherwise, it is 0 (false).

The arithmetic comparison does not cause an Integer Overflow exception.

Restrictions:

None

Operation:

```

if GPR[rs] < sign_extend(immediate) then
    GPR[rt] ← 0GPRLEN-1 || 1
else
    GPR[rt] ← 0GPRLEN
endif

```

Exceptions:

None

Format: SLTIU *rt*, *rs*, *immediate*

MIPS32

Purpose: Set on Less Than Immediate Unsigned

To record the result of an unsigned less-than comparison with a constant.

Description: $GPR[rt] \leftarrow (GPR[rs] < immediate)$

Compare the contents of GPR *rs* and the sign-extended 16-bit *immediate* as unsigned integers; record the Boolean result of the comparison in GPR *rt*. If GPR *rs* is less than *immediate*, the result is 1 (true); otherwise, it is 0 (false).

Because the 16-bit *immediate* is sign-extended before comparison, the instruction can represent the smallest or largest unsigned numbers. The representable values are at the minimum [0, 32767] or maximum [max_unsigned-32767, max_unsigned] end of the unsigned range.

The arithmetic comparison does not cause an Integer Overflow exception.

Restrictions:

None

Operation:

```

if (0 || GPR[rs]) < (0 || sign_extend(immediate)) then
    GPR[rt] ← 0GPRLEN-1 || 1
else
    GPR[rt] ← 0GPRLEN
endif

```

Exceptions:

None

6	5		5		5		5		6		

Format: SQRT.fmt

SQRT.S fd, fs

SQRT.D fd, fs

MIPS32

MIPS32

Purpose: Floating Point Square Root

To compute the square root of an FP value.

Description: $FPR[fd] \leftarrow SQRT(FPR[fs])$

The square root of the value in FPR *fs* is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operand and result are values in format *fmt*.

If the value in FPR *fs* corresponds to -0 , the result is -0 .

Restrictions:

If the value in FPR *fs* is less than 0, an Invalid Operation condition is raised.

The fields *fs* and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

`StoreFPR(fd, fmt, SquareRoot(ValueFPR(fs, fmt)))`

Exceptions:

6	5	5	5	5	5	6					

Format: SSNOP

Assembly Idiom MIPS32

Purpose: Superscalar No Operation

Break superscalar issue on a superscalar processor.

Description:

SSNOP is the assembly idiom used to denote superscalar no operation. The actual instruction is interpreted by the hardware as SLL r0, r0, 1.

This instruction alters the instruction issue behavior on a superscalar processor by forcing the SSNOP instruction to single-issue. The processor must then end the current instruction issue between the instruction previous to the SSNOP and the SSNOP. The SSNOP then issues alone in the next issue slot.

On a single-issue processor, this instruction is a NOP that takes an issue slot.

Restrictions:

None

Availability and Compatibility

Release 6: the special no-operation instruction SSNOP is deprecated: it behaves the same as a conventional NOP. Its special behavior with respect to instruction issue is no longer guaranteed. Release 6 requires interlocks ~~in most situations where SSNOP was necessary on earlier releases~~, and the SYNC and JR.HB instructions are provided if stronger serialization are needed.

Assemblers targeting specifically Release 6 should reject the SSNOP instruction with an error.

Operation:

None

Exceptions:

None

Programming Notes:

SSNOP is intended for use primarily to allow the programmer control over CP0 hazards by converting instructions into cycles in a superscalar processor. For example, to insert at least two cycles between an MTC0 and an ERET, one would use the following sequence:

```
mtc0    x,y
ssnop
ssnop
eret
```

The MTC0 issues in cycle T. Because the SSNOP instructions must issue alone, they may issue no earlier than cycle T+1 and cycle T+2, respectively. Finally, the ERET issues no earlier than cycle T+3. Although the instruction after an SSNOP may issue no earlier than the cycle after the SSNOP is issued, that instruction may issue later. This is because other implementation-dependent issue rules may apply that prevent an issue in the next cycle. Processors should not introduce any unnecessary delay in issuing SSNOP instructions.

Format: SUB rd, rs, rt

MIPS32

Purpose: Subtract Word

To subtract 32-bit integers. If overflow occurs, then trap.

Description: $GPR[rd] \leftarrow GPR[rs] - GPR[rt]$

The 32-bit word value in GPR *rt* is subtracted from the 32-bit value in GPR *rs* to produce a 32-bit result. If the subtraction results in 32-bit 2's complement arithmetic overflow, then the destination register is not modified and an Integer Overflow exception occurs. If it does not overflow, the 32-bit result is placed into GPR *rd*.

Restrictions:

None

Operation:

```
temp ← (GPR[rs]31 | GPR[rs]31..0) - (GPR[rt]31 | GPR[rt]31..0)
if temp32 ≠ temp31 then
    SignalException(IntegerOverflow)
else
    GPR[rd] ← temp31..0
endif
```

Exceptions:

Integer Overflow

Programming Notes:

SUBU performs the same arithmetic operation but does not trap on overflow.

Format: SUB.fmt
 SUB.S fd, fs, ft
 SUB.D fd, fs, ft
 SUB.PS fd, fs, ft

MIPS32

MIPS32

MIPS32 Release 2, removed in Release 6

Purpose: Floating Point Subtract

To subtract FP values.

Description: $FPR[fd] \leftarrow FPR[fs] - FPR[ft]$

The value in FPR *ft* is subtracted from the value in FPR *fs*. The result is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operands and result are values in format *fmt*. SUB.PS subtracts the upper and lower halves of FPR *fs* and FPR *ft* independently, and ORs together any generated exceptional conditions.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*. If the fields are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of SUB.PS is **UNPREDICTABLE** if the processor is executing in the FR=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility:

The SUB.PS instruction has been removed in Release 6.

Operation:

StoreFPR (fd, fmt, ValueFPR(fs, fmt) $-_{\text{fmt}}$ ValueFPR(ft, fmt))

CPU Exceptions:

Coprocessor Unusable, Reserved Instruction

FPU Exceptions:

Inexact, Overflow, Underflow, Invalid Op, Unimplemented Op

31	26	25	21	20	16	15	11	10	6	5	0
SPECIAL 000000						rs		rt		rd	
										0 00000	
										SUBU 100011	
6						5		5		5	
										6	

Format: SUBU *rd*, *rs*, *rt*

MIPS32

Purpose: Subtract Unsigned Word

To subtract 32-bit integers.

Description: $GPR[rd] \leftarrow GPR[rs] - GPR[rt]$

The 32-bit word value in GPR *rt* is subtracted from the 32-bit value in GPR *rs* and the 32-bit arithmetic result is and placed into GPR *rd*.

No integer overflow exception occurs under any circumstances.

Restrictions:

None

Operation:

```
temp ← GPR[rs] - GPR[rt]
GPR[rd] ← temp
```

Exceptions:

None

Programming Notes:

The term “unsigned” in the instruction name is a misnomer; this operation is 32-bit modulo arithmetic that does not trap on overflow. It is appropriate for unsigned arithmetic, such as address arithmetic, or integer arithmetic environments that ignore overflow, such as C language arithmetic.

31	26	25	21	20	16	15	11	10	6	5	0
COP1X 010011		base		index		fs		0 00000		SUXC1 001101	
6		5		5		5		5		6	

Format: SUXC1 fs, index(base)

MIPS32 Release 2, removed in Release 6

Purpose: Store Doubleword Indexed Unaligned from Floating Point

To store a doubleword from an FPR to memory (GPR+GPR addressing) ignoring alignment.

Description: $\text{memory}[(\text{GPR}[\text{base}] + \text{GPR}[\text{index}])_{\text{PSIZE}-1..3}] \leftarrow \text{FPR}[\text{fs}]$

The contents of the 64-bit doubleword in FPR *fs* is stored at the memory location specified by the effective address. The contents of GPR *index* and GPR *base* are added to form the effective address. The effective address is doubleword-aligned; EffectiveAddress_{2..0} are ignored.

Restrictions:

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model. The instruction is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Availability and Compatibility

This instruction has been removed in Release 6.

Operation:

```

vAddr ← (GPR[base]+GPR[index])63..3 || 03
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, STORE)
datadoubleword ← ValueFPR(fs, UNINTERPRETED_DOUBLEWORD)
paddr ← paddr xor ((BigEndianCPU xor ReverseEndian) || 02)
StoreMemory(CCA, WORD, datadoubleword31..0, pAddr, vAddr, DATA)
paddr ← paddr xor 0b100
StoreMemory(CCA, WORD, datadoubleword63..32, pAddr, vAddr+4, DATA)

```

Exceptions:

Coprocessor Unusable, Reserved Instruction, TLB Refill, TLB Invalid, TLB Modified, Watch

Format: SW *rt*, *offset*(*base*)

MIPS32

Purpose: Store Word

To store a word to memory.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{GPR}[\text{rt}]$

The least-significant 32-bit word of GPR *rt* is stored in memory at the location specified by the aligned effective address. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

Pre-Release 6: The effective address must be naturally-aligned. If either of the 2 least-significant bits of the address is non-zero, an Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses”](#) on page 511.

Operation:

```
vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
dataword ← GPR[rt]
StoreMemory (CCA, WORD, dataword, pAddr, vAddr, DATA)
```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Address Error, Watch

SWC1 *ft*, *offset*(*base*)

MIPS32

Purpose: Store Word from Floating Point

To store a word from an FPR to memory.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{FPR}[\text{ft}]$

The low 32-bit word from FPR *ft* is stored in memory at the location specified by the aligned effective address. The 16-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

Pre-Release 6: An Address Error exception occurs if $\text{EffectiveAddress}_{1..0} \neq 0$ (not word-aligned).

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses”](#) on page 511.

Operation:

```
vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, STORE)
dataword ← ValueFPR(ft, UNINTERPRETED_WORD)
StoreMemory(CCA, WORD, dataword, pAddr, vAddr, DATA)
```

Exceptions:

Coprocessor Unusable, Reserved Instruction, TLB Refill, TLB Invalid, TLB Modified, Address Error, Watch

pre-Release 6

Release 6

**Format:** SWC2 rt, offset(base)**MIPS32****Purpose:** Store Word from Coprocessor 2

To store a word from a COP2 register to memory

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{CPR}[2, \text{rt}, 0]$

The low 32-bit word from COP2 (Coprocessor 2) register *rt* is stored in memory at the location specified by the aligned effective address. The signed *offset* is added to the contents of GPR *base* to form the effective address.

Restrictions:

Pre-Release 6: An Address Error exception occurs if $\text{EffectiveAddress}_{1..0} \neq 0$ (not word-aligned).

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses” on page 511](#).

Availability and Compatibility:

This instruction has been reallocated an opcode in Release 6.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, STORE)
dataword ← CPR[2,rt,0]
StoreMemory(CCA, WORD, dataword, pAddr, vAddr, DATA)

```

Exceptions:

Coprocessor Unusable, Reserved Instruction, TLB Refill, TLB Invalid, TLB Modified, Address Error, Watch

Programming Notes:

As shown in the instruction drawing above, Release 6 implements an 11-bit offset, whereas all release levels lower than Release 6 of the MIPS architecture implement a 16-bit offset.

Format: SWE *rt*, *offset*(*base*)

MIPS32

Purpose: Store Word EVA

To store a word to user mode virtual address space when executing in kernel mode.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{GPR}[\text{rt}]$

The least-significant 32-bit word of GPR *rt* is stored in memory at the location specified by the aligned effective address. The 9-bit signed *offset* is added to the contents of GPR *base* to form the effective address.

The SWE instruction functions the same as the SW instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to 1.

Restrictions:

Only usable in kernel mode when accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

Pre-Release 6: The effective address must be naturally-aligned. If either of the 2 least-significant bits of the address is non-zero, an Address Error exception occurs.

Release 6 requires systems to provide support for misaligned memory accesses for all ordinary memory reference instructions. This instruction is considered an ordinary memory reference instruction for the purposes of misalignment: the system must provide a mechanism to complete a misaligned memory reference for this instruction, ranging from full execution in hardware to trap-and-emulate.

Note: The pseudocode in this instruction description may not yet have been updated to reflect misalignment support; the pseudocode may still indicate a required exception, which is now optional. See [Appendix B, “Misaligned Memory Accesses” on page 511](#).

Operation:

```
vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
dataword ← GPR[rt]
StoreMemory (CCA, WORD, dataword, pAddr, vAddr, DATA)
```

Exceptions:

TLB Refill

TLB Invalid

Bus Error

Address Error

Watch

Reserved Instruction

Coprocessor Unusable

Format: SWL *rt*, *offset*(*base*)

MIPS32, removed in Release 6

Purpose: Store Word Left

To store the most-significant part of a word to an unaligned memory address.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{GPR}[\text{rt}]$

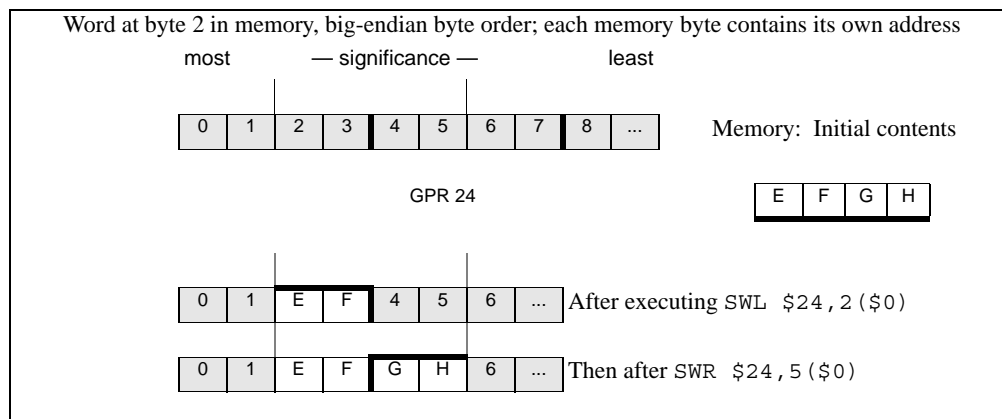

The 16-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the most-significant of 4 consecutive bytes forming a word (*W*) in memory starting at an arbitrary byte boundary.

A part of *W* (the most-significant 1 to 4 bytes) is in the aligned word containing *EffAddr*. The same number of the most-significant (left) bytes from the word in GPR *rt* are stored into these bytes of *W*.

The following figure illustrates this operation using big-endian byte ordering for 32-bit and 64-bit registers. The four consecutive bytes in 2..5 form an unaligned word starting at location 2. A part of *W* (2 bytes) is located in the aligned word containing the most-significant byte at 2.

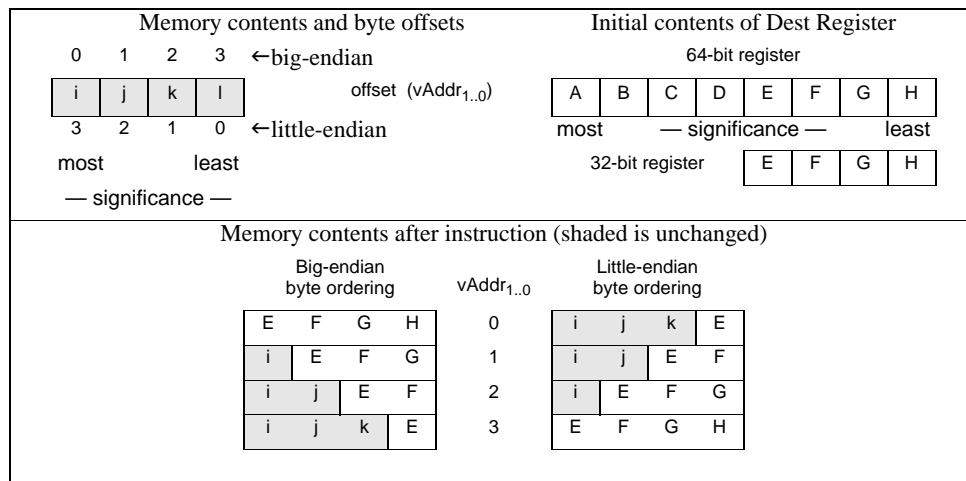

- SWL stores the most-significant 2 bytes of the low word from the source register into these 2 bytes in memory.
- The complementary SWR stores the remainder of the unaligned word.

Figure 5.9 Unaligned Word Store Using SWL and SWR

The bytes stored from the source register to memory depend on both the offset of the effective address within an aligned word—that is, the low 2 bits of the address ($vAddr_{l,0}$)—and the current byte-ordering mode of the processor (big- or little-endian). The following figure shows the bytes stored for every combination of offset and byte ordering.

Figure 5.10 Bytes Stored by an SWL Instruction

**Restrictions:**

None

Availability and Compatibility:

Release 6 removes the load/store-left/right family of instructions, and requires the system to support misaligned memory accesses.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
pAddr ← pAddrPSIZE-1..2 || (pAddr1..0 xor ReverseEndian2)
If BigEndianMem = 0 then
    pAddr ← pAddrPSIZE-1..2 || 02
endif
byte ← vAddr1..0 xor BigEndianCPU2
dataword ← 024-8*byte || GPR[rt]31..24-8*byte
StoreMemory(CCA, byte, dataword, pAddr, vAddr, DATA)

```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Bus Error, Address Error, Watch

Format: SWLE *rt*, *offset*(*base*)

MIPS32, removed in Release 6

Purpose: Store Word Left EVA

To store the most-significant part of a word to an unaligned user mode virtual address while operating in kernel mode.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{GPR}[\text{rt}]$

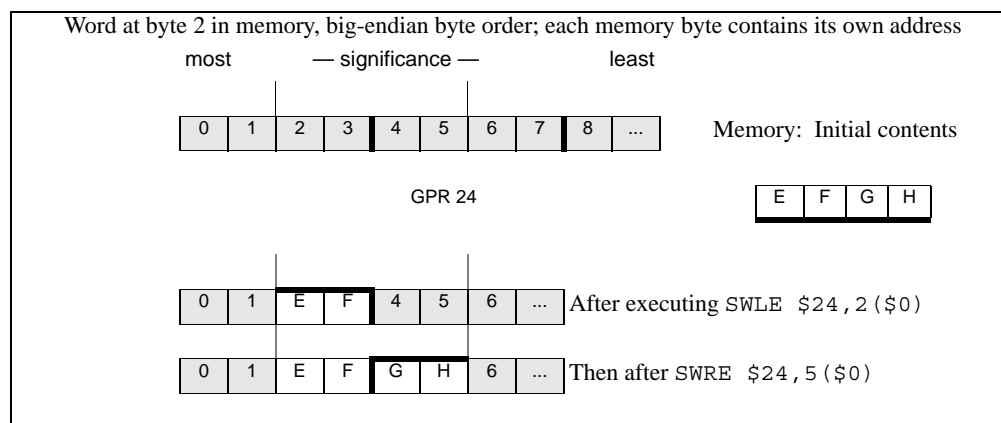

The 9-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the most-significant of 4 consecutive bytes forming a word (*W*) in memory starting at an arbitrary byte boundary.

A part of *W* (the most-significant 1 to 4 bytes) is in the aligned word containing *EffAddr*. The same number of the most-significant (left) bytes from the word in GPR *rt* are stored into these bytes of *W*.

The following figure shows this operation using big-endian byte ordering for 32-bit and 64-bit registers. The 4 consecutive bytes in 2..5 form an unaligned word starting at location 2. A part of *W* (2 bytes) is located in the aligned word containing the most-significant byte at 2.

1. SWLE stores the most-significant 2 bytes of the low word from the source register into these 2 bytes in memory.
2. The complementary SWRE stores the remainder of the unaligned word.

Figure 5.11 Unaligned Word Store Using SWLE and SWRE

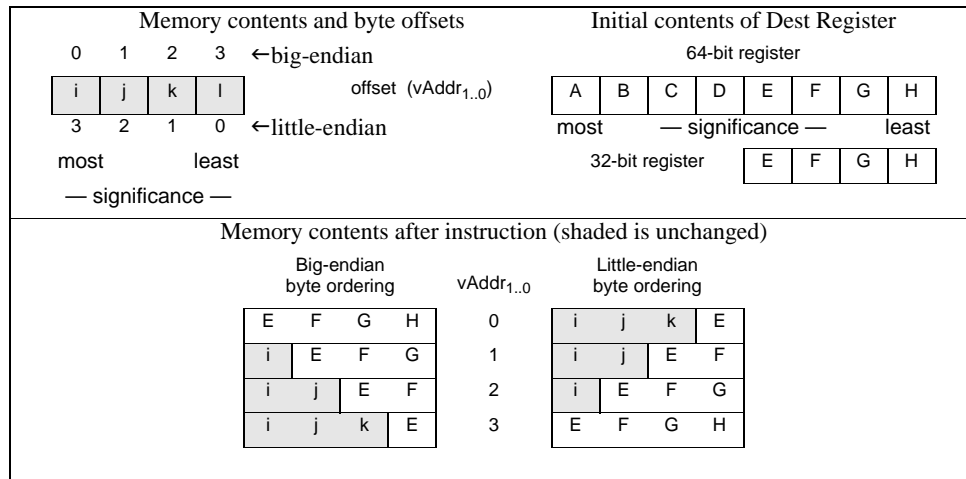

The bytes stored from the source register to memory depend on both the offset of the effective address within an aligned word—that is, the low 2 bits of the address ($vAddr_{1..0}$)—and the current byte-ordering mode of the processor (big- or little-endian). The following figure shows the bytes stored for every combination of offset and byte ordering.

The SWLE instruction functions the same as the SWL instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to 1.

Figure 5.12 Bytes Stored by an SWLE Instruction

**Restrictions:**

Only usable when access to Coprocessor0 is enabled and when accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

Availability and Compatibility:

Release 6 removes the load/store-left/right family of instructions, and requires the system to support misaligned memory accesses.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
pAddr ← pAddrPSIZE-1..2 || (pAddr1..0 xor ReverseEndian2)
If BigEndianMem = 0 then
    pAddr ← pAddrPSIZE-1..2 || 02
endif
byte ← vAddr1..0 xor BigEndianCPU2
dataword ← 024-8*byte || GPR[rt]31..24-8*byte
StoreMemory(CCA, byte, dataword, pAddr, vAddr, DATA)

```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Bus Error, Address Error, Watch, Reserved Instruction, Coprocessor Unusable

Format: SWR *rt*, *offset*(*base*)

MIPS32, removed in Release 6

Purpose: Store Word Right

To store the least-significant part of a word to an unaligned memory address.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{GPR}[\text{rt}]$

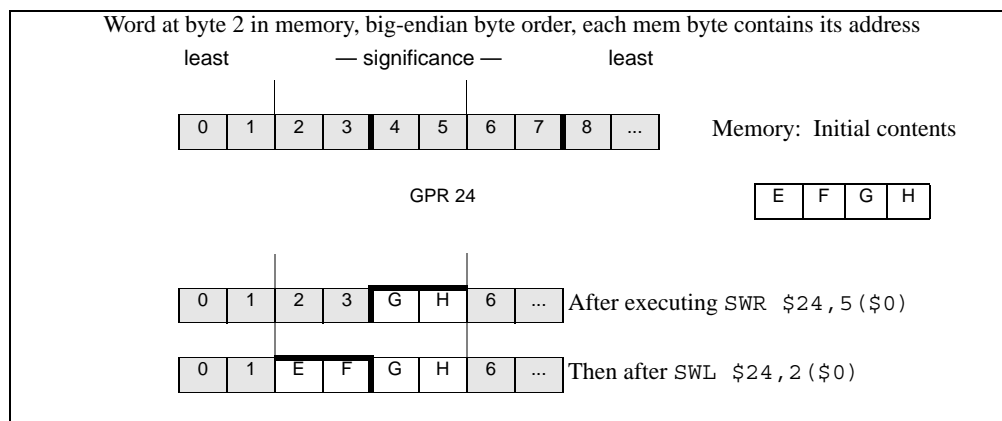

The 16-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the least-significant of 4 consecutive bytes forming a word (*W*) in memory starting at an arbitrary byte boundary.

A part of *W* (the least-significant 1 to 4 bytes) is in the aligned word containing *EffAddr*. The same number of the least-significant (right) bytes from the word in GPR *rt* are stored into these bytes of *W*.

The following figure illustrates this operation using big-endian byte ordering for 32-bit and 64-bit registers. The 4 consecutive bytes in 2..5 form an unaligned word starting at location 2. A part of *W* (2 bytes) is contained in the aligned word containing the least-significant byte at 5.

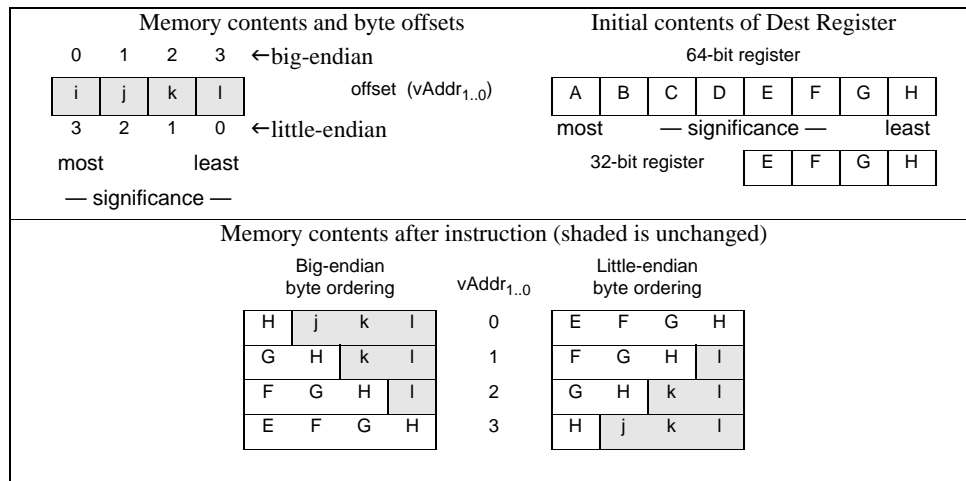

1. SWR stores the least-significant 2 bytes of the low word from the source register into these 2 bytes in memory.
2. The complementary SWL stores the remainder of the unaligned word.

Figure 5.13 Unaligned Word Store Using SWR and SWL

The bytes stored from the source register to memory depend on both the offset of the effective address within an aligned word—that is, the low 2 bits of the address ($vAddr_{1..0}$)—and the current byte-ordering mode of the processor (big- or little-endian). The following figure shows the bytes stored for every combination of offset and byte-ordering.

**Restrictions:**

None

Availability and Compatibility:

Release 6 removes the load/store-left/right family of instructions, and requires the system to support misaligned memory accesses.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
pAddr ← pAddrPSIZE-1..2 || (pAddr1..0 xor ReverseEndian2)
If BigEndianMem = 0 then
    pAddr ← pAddrPSIZE-1..2 || 02
endif
byte ← vAddr1..0 xor BigEndianCPU2
dataword ← GPR[rt]31-8*byte || 08*byte
StoreMemory(CCA, WORD-byte, dataword, pAddr, vAddr, DATA)

```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Bus Error, Address Error, Watch

Format: SWRE *rt*, *offset*(*base*)

MIPS32, removed in Release 6

Purpose: Store Word Right EVA

To store the least-significant part of a word to an unaligned user mode virtual address while operating in kernel mode.

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{offset}] \leftarrow \text{GPR}[\text{rt}]$

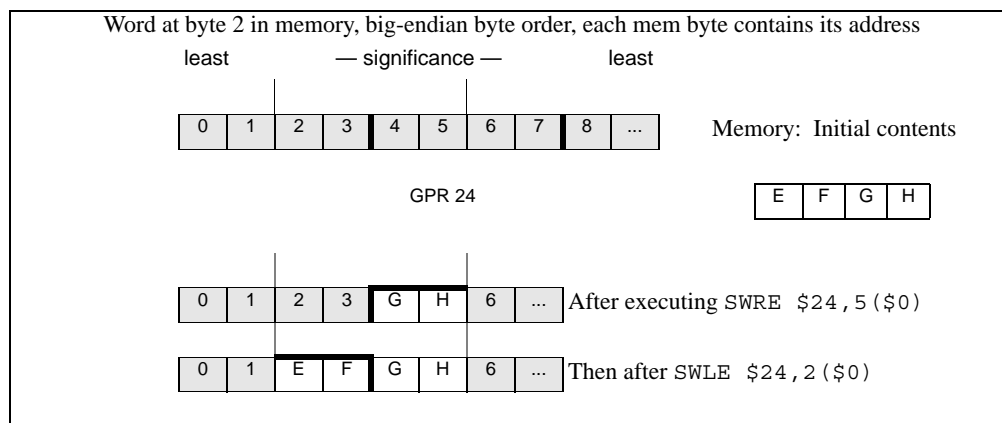

The 9-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the least-significant of 4 consecutive bytes forming a word (*W*) in memory starting at an arbitrary byte boundary.

A part of *W* (the least-significant 1 to 4 bytes) is in the aligned word containing *EffAddr*. The same number of the least-significant (right) bytes from the word in GPR *rt* are stored into these bytes of *W*.

The following figure illustrates this operation using big-endian byte ordering for 32-bit and 64-bit registers. The 4 consecutive bytes in 2..5 form an unaligned word starting at location 2. A part of *W* (2 bytes) is contained in the aligned word containing the least-significant byte at 5.

3. SWRE stores the least-significant 2 bytes of the low word from the source register into these 2 bytes in memory.
4. The complementary SWLE stores the remainder of the unaligned word.

Figure 5.15 Unaligned Word Store Using SWRE and SWLE

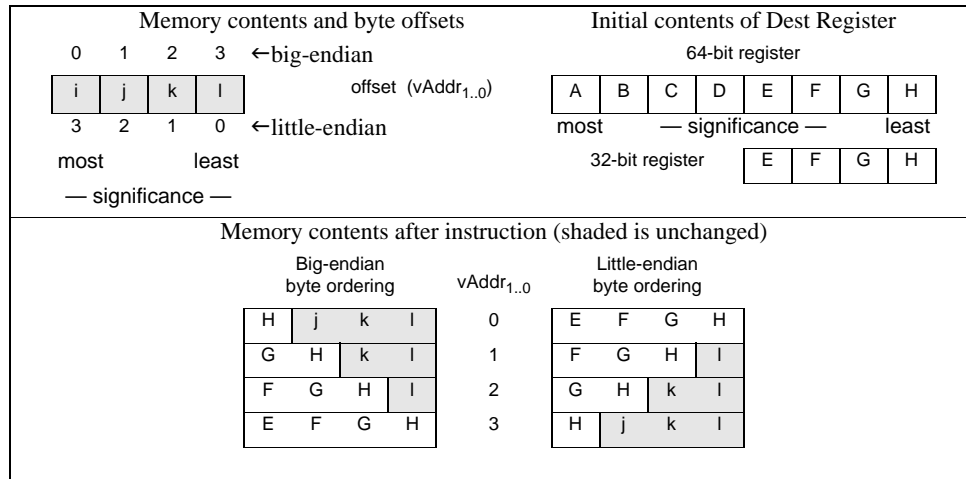

The bytes stored from the source register to memory depend on both the offset of the effective address within an aligned word—that is, the low 2 bits of the address ($vAddr_{L..0}$)—and the current byte-ordering mode of the processor (big- or little-endian). The following figure shows the bytes stored for every combination of offset and byte-ordering.

The LWE instruction functions the same as the LW instruction, except that address translation is performed using the user mode virtual address space mapping in the TLB when accessing an address within a memory segment configured to use the MUSUK access mode. Memory segments using UUSK or MUSK access modes are also accessible. Refer to Volume III, Enhanced Virtual Addressing section for additional information.

Implementation of this instruction is specified by the *Config5_{EVA}* field being set to 1.

Figure 5.16 Bytes Stored by SWRE Instruction

**Restrictions:**

Only usable when access to Coprocessor0 is enabled and when accessing an address within a segment configured using UUSK, MUSK or MUSUK access mode.

Availability and Compatibility:

Release 6 removes the load/store-left/right family of instructions, and requires the system to support misaligned memory accesses.

Operation:

```

vAddr ← sign_extend(offset) + GPR[base]
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
pAddr ← pAddrPSIZE-1..2 || (pAddr1..0 xor ReverseEndian2)
If BigEndianMem = 0 then
    pAddr ← pAddrPSIZE-1..2 || 02
endif
byte ← vAddr1..0 xor BigEndianCPU2
dataword ← GPR[rt]31-8*byte || 08*byte
StoreMemory(CCA, WORD-byte, dataword, pAddr, vAddr, DATA)

```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Bus Error, Address Error, Watch, Coprocessor Unusable

Format: SWXC1 fs, index(base)

removed in Release 6
MIPS32 Release 2, removed in Release 6

Purpose: Store Word Indexed from Floating Point

To store a word from an FPR to memory (GPR+GPR addressing)

Description: $\text{memory}[\text{GPR}[\text{base}] + \text{GPR}[\text{index}]] \leftarrow \text{FPR}[\text{fs}]$

The low 32-bit word from FPR *fs* is stored in memory at the location specified by the aligned effective address. The contents of GPR *index* and GPR *base* are added to form the effective address.

Restrictions:

An Address Error exception occurs if $\text{EffectiveAddress}_{1..0} \neq 0$ (not word-aligned).

Availability and Compatibility:

This instruction has been removed in Release 6.

Required in all versions of MIPS64 since MIPS64 Release 1. Not available in MIPS32 Release 1. Required in MIPS32 Release 2 and all subsequent versions of MIPS32. When required, required whenever FPU is present, whether a 32-bit or 64-bit FPU, whether in 32-bit or 64-bit FP Register Mode ($\text{FIR}_{F64}=0$ or 1, $\text{Status}_{FR}=0$ or 1).

Operation:

```

vAddr ← GPR[base] + GPR[index]
if vAddr1..0 ≠ 03 then
    SignalException(AddressError)
endif
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, STORE)
dataword ← ValueFPR(fs, UNINTERPRETED_WORD)
StoreMemory(CCA, WORD, dataword, pAddr, vAddr, DATA)

```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Address Error, Reserved Instruction, Coprocessor Unusable, Watch

6			15				5		6		

Format: SYNC (stype = 0 implied)
SYNC stype

MIPS32
MIPS32

Purpose: Synchronize Shared Memory

To order loads and stores for shared memory.

Description:

These types of ordering guarantees are available through the SYNC instruction:

- Completion Barriers
- Ordering Barriers

Completion Barrier — Simple Description:

- The barrier affects only *uncached* and *cached coherent* loads and stores.
- The specified memory instructions (loads or stores or both) that occur before the SYNC instruction must be completed before the specified memory instructions after the SYNC are allowed to start.
- Loads are completed when the destination register is written. Stores are completed when the stored value is visible to every other processor in the system.

Completion Barrier — Detailed Description:

- Every synchronizable specified memory instruction (loads or stores or both) that occurs in the instruction stream before the SYNC instruction must be already globally performed before any synchronizable specified memory instructions that occur after the SYNC are allowed to be performed, with respect to any other processor or coherent I/O module.
- The barrier does not guarantee the order in which instruction fetches are performed.
- A stype value of zero will always be defined such that it performs the most complete set of synchronization operations that are defined. This means stype zero always does a completion barrier that affects both loads and stores preceding the SYNC instruction and both loads and stores that are subsequent to the SYNC instruction. Non-zero values of stype may be defined by the architecture or specific implementations to perform synchronization behaviors that are less complete than that of stype zero. If an implementation does not use one of these non-zero values to define a different synchronization behavior, then that non-zero value of stype must act the same as stype zero completion barrier. This allows software written for an implementation with a lighter-weight barrier to work on another implementation which only implements the stype zero completion barrier.
- A completion barrier is required, potentially in conjunction with SSNOP (in Release 1 of the Architecture) or EHB (in Release 2 of the Architecture), to guarantee that memory reference results are visible across operating mode changes. For example, a completion barrier is required on some implementations on entry to and exit from Debug Mode to guarantee that memory effects are handled correctly.

SYNC behavior when the stype field is zero:

- A completion barrier that affects preceding loads and stores and subsequent loads and stores.

Ordering Barrier — Simple Description:

- The barrier affects only *uncached* and *cached coherent* loads and stores.
- The specified memory instructions (loads or stores or both) that occur before the SYNC instruction must always be ordered before the specified memory instructions after the SYNC.
- Memory instructions which are ordered before other memory instructions are processed by the load/store datapath first before the other memory instructions.

Ordering Barrier — Detailed Description:

- Every synchronizable specified memory instruction (loads or stores or both) that occurs in the instruction stream before the SYNC instruction must reach a stage in the load/store datapath after which no instruction re-ordering is possible before any synchronizable specified memory instruction which occurs after the SYNC instruction in the instruction stream reaches the same stage in the load/store datapath.
- If any memory instruction before the SYNC instruction in program order, generates a memory request to the external memory and any memory instruction after the SYNC instruction in program order also generates a memory request to external memory, the memory request belonging to the older instruction must be globally performed before the time the memory request belonging to the younger instruction is globally performed.
- The barrier does not guarantee the order in which instruction fetches are performed.

As compared to the completion barrier, the ordering barrier is a lighter-weight operation as it does not require the specified instructions before the SYNC to be already completed. Instead it only requires that those specified instructions which are subsequent to the SYNC in the instruction stream are never re-ordered for processing ahead of the specified instructions which are before the SYNC in the instruction stream. This potentially reduces how many cycles the barrier instruction must stall before it completes.

The Acquire and Release barrier types are used to minimize the memory orderings that must be maintained and still have software synchronization work.

Implementations that do not use any of the non-zero values of stype to define different barriers, such as ordering barriers, must make those stype values act the same as stype zero.

For the purposes of this description, the CACHE, PREF and PREFX instructions are treated as loads and stores. That is, these instructions and the memory transactions sourced by these instructions obey the ordering and completion rules of the SYNC instruction.

Table 5.5 lists the available completion barrier and ordering barriers behaviors that can be specified using the stype field.

Table 5.5 Encodings of the Bits[10:6] of the SYNC instruction; the STYPE Field

Code	Name	Older instructions which must reach the load/store ordering point before the SYNC instruction completes. Terms:

Synchronizable: A load or store instruction is *synchronizable* if the load or store occurs to a physical location in shared memory using a virtual location with a memory access type of either *uncached* or *cached coherent*. *Shared memory* is memory that can be accessed by more than one processor or by a coherent I/O system module.

Performed load: A load instruction is *performed* when the value returned by the load has been determined. The result of a load on processor A has been *determined* with respect to processor or coherent I/O module B when a subsequent store to the location by B cannot affect the value returned by the load. The store by B must use the same memory access type as the load.

Performed store: A store instruction is *performed* when the store is observable. A store on processor A is *observable* with respect to processor or coherent I/O module B when a subsequent load of the location by B returns the value

written by the store. The load by B must use the same memory access type as the store.

Globally performed load: A load instruction is *globally performed* when it is performed with respect to all processors and coherent I/O modules capable of storing to the location.

Globally performed store: A store instruction is *globally performed* when it is globally observable. It is *globally observable* when it is observable by all processors and I/O modules capable of loading from the location.

Coherent I/O module: A *coherent I/O module* is an Input/Output system component that performs coherent Direct Memory Access (DMA). It reads and writes memory independently as though it were a processor doing loads and stores to locations with a memory access type of *cached coherent*.

Load/Store Datapath: The portion of the processor which handles the load/store data requests coming from the processor pipeline and processes those requests within the cache and memory system hierarchy.

Restrictions:

The effect of SYNC on the global order of loads and stores for memory access types other than *uncached* and *cached coherent* is **UNPREDICTABLE**.

Operation:

SyncOperation(stype)

Exceptions:

None

Programming Notes:

A processor executing load and store instructions observes the order in which loads and stores using the same memory access type occur in the instruction stream; this is known as *program order*.

A *parallel program* has multiple instruction streams that can execute simultaneously on different processors. In multiprocessor (MP) systems, the order in which the effects of loads and stores are observed by other processors—the *global order* of the loads and store—determines the actions necessary to reliably share data in parallel programs.

When all processors observe the effects of loads and stores in program order, the system is *strongly ordered*. On such systems, parallel programs can reliably share data without explicit actions in the programs. For such a system, SYNC has the same effect as a NOP. Executing SYNC on such a system is not necessary, but neither is it an error.

If a multiprocessor system is not strongly ordered, the effects of load and store instructions executed by one processor may be observed out of program order by other processors. On such systems, parallel programs must take explicit actions to reliably share data. At critical points in the program, the effects of loads and stores from an instruction stream must occur in the same order for all processors. SYNC separates the loads and stores executed on the processor into two groups, and the effect of all loads and stores in one group is seen by all processors before the effect of any load or store in the subsequent group. In effect, SYNC causes the system to be strongly ordered for the executing processor at the instant that the SYNC is executed.

Many MIPS-based multiprocessor systems are strongly ordered or have a mode in which they operate as strongly ordered for at least one memory access type. The MIPS architecture also permits implementation of MP systems that are not strongly ordered; SYNC enables the reliable use of shared memory on such systems. A parallel program that does not use SYNC generally does not operate on a system that is not strongly ordered. However, a program that does use SYNC works on both types of systems. (System-specific documentation describes the actions needed to reliably share data in parallel programs for that system.)

The behavior of a load or store using one memory access type is **UNPREDICTABLE** if a load or store was previously made to the same physical location using a different memory access type. The presence of a SYNC between the references does not alter this behavior.

SYNC affects the order in which the effects of load and store instructions appear to all processors; it does not gener-

ally affect the physical memory-system ordering or synchronization issues that arise in system programming. The effect of SYNC on implementation-specific aspects of the cached memory system, such as writeback buffers, is not defined.

```
# Processor A (writer)
# Conditions at entry:
# The value 0 has been stored in FLAG and that value is observable by B
SW    R1, DATA      # change shared DATA value
LI    R2, 1
SYNC                      # Perform DATA store before performing FLAG store
SW    R2, FLAG        # say that the shared DATA value is valid

# Processor B (reader)
LI    R2, 1
1: LW   R1, FLAG      # Get FLAG
BNE    R2, R1, 1B     # if it says that DATA is not valid, poll again
NOP
SYNC                      # FLAG value checked before doing DATA read
LW    R1, DATA      # Read (valid) shared DATA value
```

The code fragments above shows how SYNC can be used to coordinate the use of shared data between separate writer and reader instruction streams in a multiprocessor environment. The FLAG location is used by the instruction streams to determine whether the shared data item DATA is valid. The SYNC executed by processor A forces the store of DATA to be performed globally before the store to FLAG is performed. The SYNC executed by processor B ensures that DATA is not read until after the FLAG value indicates that the shared data is valid.

Software written to use a SYNC instruction with a non-zero stype value, expecting one type of barrier behavior, should only be run on hardware that actually implements the expected barrier behavior for that non-zero stype value or on hardware which implements a superset of the behavior expected by the software for that stype value. If the hardware does not perform the barrier behavior expected by the software, the system may fail.

31	26	25	21	20	16	15	0
REGIMM 000001				base		SYNCI 11111	
						offset	
6				5		5	
						16	

Format: SYNCI offset (base)

MIPS32 Release 2

Purpose:

Synchronize Caches to Make Instruction Writes Effective

To synchronize all caches to make instruction writes effective.

Description:

This instruction is used after a new instruction stream is written to make the new instructions effective relative to an instruction fetch, when used in conjunction with the SYNC and JALR.HB, JR.HB, or ERET instructions, as described below. Unlike the CACHE instruction, the SYNCI instruction is available in all operating modes in an implementation of Release 2 of the architecture.

The 16-bit offset is sign-extended and added to the contents of the base register to form an effective address. The effective address is used to address the cache line in all caches which may need to be synchronized with the write of the new instructions. The operation occurs only on the cache line which may contain the effective address. One SYNCI instruction is required for every cache line that was written. See the Programming Notes below.

A TLB Refill and TLB Invalid (both with cause code equal TLBL) exception can occur as a by product of this instruction. This instruction never causes TLB Modified exceptions nor TLB Refill exceptions with a cause code of TLBS. This instruction never causes Execute-Inhibit nor Read-Inhibit exceptions.

A Cache Error exception may occur as a by product of this instruction. For example, if a writeback operation detects a cache or bus error during the processing of the operation, that error is reported via a Cache Error exception. Similarly, a Bus Error Exception may occur if a bus operation invoked by this instruction is terminated in an error.

An Address Error Exception (with cause code equal AdEL) may occur if the effective address references a portion of the kernel address space which would normally result in such an exception. It is implementation dependent whether such an exception does occur.

It is implementation dependent whether a data watch is triggered by a SYNCI instruction whose address matches the Watch register address match conditions.

Restrictions:

The operation of the processor is **UNPREDICTABLE** if the effective address references any instruction cache line that contains instructions to be executed between the SYNCI and the subsequent JALR.HB, JR.HB, or ERET instruction required to clear the instruction hazard.

The SYNCI instruction has no effect on cache lines that were previously locked with the CACHE instruction. If correct software operation depends on the state of a locked line, the CACHE instruction must be used to synchronize the caches.

Full visibility of the new instruction stream requires execution of a subsequent SYNC instruction, followed by a JALR.HB, JR.HB, DERET, or ERET instruction. The operation of the processor is **UNPREDICTABLE** if this sequence is not followed.

SYNCI globalization:

Release 6: SYNCI *globalization* (as described below) is required: compliant implementations must globalize SYNCI. Portable software can rely on this behavior, and use SYNCI rather than expensive “instruction cache shutdown” using inter-processor interrupts.

Pre-Release 6: portable software could not rely on the optional *globalization* (see below) of SYNCI meant that strictly portable software without implementation specific awareness could only rely on expensive “instruction cache

shutdown using inter-processor interrupts.

The SYNCI instruction acts on the current processor at a minimum. Implementations are required to affect caches outside the current processor to perform the operation on the current processor (as might be the case if multiple processors share an L2 or L3 cache).

In multiprocessor implementations where instruction caches are coherently maintained by hardware, the SYNCI instruction should behave as a NOP instruction.

In multiprocessor implementations where instruction caches are not coherently maintained by hardware, the SYNCI instruction may optionally affect all coherent icaches within the system. If the effective address uses a coherent Cacheability and Coherency Attribute (CCA), then the operation may be *globalized*, meaning it is broadcast to all of the coherent instruction caches within the system. If the effective address does not use one of the coherent CCAs, there is no broadcast of the SYNCI operation. If multiple levels of caches are to be affected by one SYNCI instruction, all of the affected cache levels must be processed in the same manner - either all affected cache levels use the globalized behavior or all affected cache levels use the non-globalized behavior.

Operation:

```
vaddr ← GPR[base] + sign_extend(offset)
SynchronizeCacheLines(vaddr)      /* Operate on all caches */
```

Exceptions:

Reserved Instruction Exception (Release 1 implementations only)

TLB Refill Exception

TLB Invalid Exception

Address Error Exception

Cache Error Exception

Bus Error Exception

Programming Notes:

When the instruction stream is written, the SYNCI instruction should be used in conjunction with other instructions to make the newly-written instructions effective. The following example shows a routine which can be called after the new instruction stream is written to make those changes effective. The SYNCI instruction could be replaced with the corresponding sequence of CACHE instructions (when access to Coprocessor 0 is available), and that the JR.HB instruction could be replaced with JALR.HB, ERET, or DERET instructions, as appropriate. A SYNC instruction is required between the final SYNCI instruction in the loop and the instruction that clears instruction hazards.

```
/*
 * This routine makes changes to the instruction stream effective to the
 * hardware. It should be called after the instruction stream is written.
 * On return, the new instructions are effective.
 *
 * Inputs:
 *   a0 = Start address of new instruction stream
 *   a1 = Size, in bytes, of new instruction stream
 */

    beq    a1, zero, 20f          /* If size==0, */
    nop                                /* branch around */
    addu   a1, a0, a1             /* Calculate end address + 1 */
    rdhwr  v0, HW_SYNCI_Step      /* Get step size for SYNCI from new */
                                /* Release 2 instruction */
    beq    v0, zero, 20f          /* If no caches require synchronization, */
    nop                                /* branch around */
10: synci 0(a0)                  /* Synchronize all caches around address */
```

```
    addu    a0, a0, v0        /* Add step size in delay slot */
    sltu    v1, a0, a1        /* Compare current with end address */
    bne     v1, zero, 10b     /* Branch if more to do */
    nop                     /*   branch around */
    sync                      /* Clear memory hazards */
20: jr.hb   ra                /* Return, clearing instruction hazards */
    nop
```

31	26	25	6	5	0
SPECIAL 000000			code		SYSCALL 001100
6			20		6

Format: SYSCALL

MIPS32

Purpose: System Call

To cause a System Call exception.

Description:

A system call exception occurs, immediately and unconditionally transferring control to the exception handler.

The *code* field is available for use as software parameters, but is retrieved by the exception handler only by loading the contents of the memory word containing the instruction.

Restrictions:

None

Operation:

`SignalException(SystemCall)`

Exceptions:

System Call

Format: TEQ *rs*, *rt*

MIPS32

Purpose: Trap if Equal

To compare GPRs and do a conditional trap.

Description: if GPR[*rs*] = GPR[*rt*] then Trap

Compare the contents of GPR *rs* and GPR *rt* as signed integers. If GPR *rs* is equal to GPR *rt*, then take a Trap exception.

The contents of the *code* field are ignored by hardware and may be used to encode information for system software. To retrieve the information, system software must load the instruction word from memory.

Restrictions:

None

Operation:

```
if GPR[rs] = GPR[rt] then
    SignalException(Trap)
endif
```

Exceptions:

Trap

Format: TEQI rs, immediate

MIPS32, removed in Release 6

Purpose: Trap if Equal Immediate

To compare a GPR to a constant and do a conditional trap.

Description: if GPR[rs] = immediate then Trap

Compare the contents of GPR *rs* and the 16-bit signed *immediate* as signed integers. If GPR *rs* is equal to *immediate*, then take a Trap exception.

Restrictions:

None

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```
if GPR[rs] = sign_extend(immediate) then
    SignalException(Trap)
endif
```

Exceptions:

Trap

Format: TGE *rs*, *rt*

MIPS32

Purpose: Trap if Greater or Equal

To compare GPRs and do a conditional trap.

Description: if GPR[*rs*] ≥ GPR[*rt*] then Trap

Compare the contents of GPR *rs* and GPR *rt* as signed integers. If GPR *rs* is greater than or equal to GPR *rt*, then take a Trap exception.

The contents of the *code* field are ignored by hardware and may be used to encode information for system software. To retrieve the information, the system software must load the instruction word from memory.

Restrictions:

None

Operation:

```
if GPR[rs] ≥ GPR[rt] then
    SignalException(Trap)
endif
```

Exceptions:

Trap

Format: TGEI rs, immediate

MIPS32, removed in Release 6

Purpose: Trap if Greater or Equal Immediate

To compare a GPR to a constant and do a conditional trap.

Description: if `GPR[rs] ≥ immediate` then Trap

Compare the contents of GPR *rs* and the 16-bit signed *immediate* as signed integers. If GPR *rs* is greater than or equal to *immediate*, then take a Trap exception.

Restrictions:

None

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```
if GPR[rs] ≥ sign_extend(immediate) then
    SignalException(Trap)
endif
```

Exceptions:

Trap

Format: TGEIU rs, immediate

MIPS32, removed in Release 6

Purpose: Trap if Greater or Equal Immediate Unsigned

To compare a GPR to a constant and do a conditional trap.

Description: if `GPR[rs] ≥ immediate` then Trap

Compare the contents of GPR *rs* and the 16-bit sign-extended *immediate* as unsigned integers. If GPR *rs* is greater than or equal to *immediate*, then take a Trap exception.

Because the 16-bit *immediate* is sign-extended before comparison, the instruction can represent the smallest or largest unsigned numbers. The representable values are at the minimum [0, 32767] or maximum [max_unsigned-32767, max_unsigned] end of the unsigned range.

Restrictions:

None

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```
if (0 || GPR[rs]) ≥ (0 || sign_extend(immediate)) then
    SignalException(Trap)
endif
```

Exceptions:

Trap

SPECIAL 000000			rs		rt		code		TGEU 110001	
6			5		5		10		6	

Format: TGEU *rs*, *rt*

MIPS32

Purpose: Trap if Greater or Equal Unsigned

To compare GPRs and do a conditional trap.

Description: if $\text{GPR}[\text{rs}] \geq \text{GPR}[\text{rt}]$ then Trap

Compare the contents of GPR *rs* and GPR *rt* as unsigned integers. If GPR *rs* is greater than or equal to GPR *rt*, then take a Trap exception.

The contents of the *code* field are ignored by hardware and may be used to encode information for system software. To retrieve the information, the system software must load the instruction word from memory.

Restrictions:

None

Operation:

```
if (0 || GPR[rs]) ≥ (0 || GPR[rt]) then
    SignalException(Trap)
endif
```

Exceptions:

Trap

31	26	25	24		6	5	0
COP0 010000	CO 1	0 000 0000 0000 0000 0000				TLBINV 000011	
6	1	19				6	

Format: TLBINV

MIPS32

Purpose: TLB Invalidate

TLBINV invalidates a set of TLB entries based on ASID and Index match. The virtual address is ignored in the entry match. TLB entries which have their G bit set to 1 are not modified.

Implementation of the TLBINV instruction is optional. The implementation of this instruction is indicated by the IE field in *Config4*.

Support for TLBINV is recommend for implementations supporting VTLB/FTLB type of MMU.

Implementation of *EntryHI_{EHINV}* field is required for implementation of TLBGINV instruction.

Description:

On execution of the TLBINV instruction, the set of TLB entries with matching ASID are marked invalid, excluding those TLB entries which have their G bit set to 1.

The *EntryHI_{ASID}* field has to be set to the appropriate ASID value before executing the TLBINV instruction.

Behavior of the TLBINV instruction applies to all applicable TLB entries and is unaffected by the setting of the *Wired* register.

- For JTLB-based MMU (*Config_{MT}*=1):

All matching entries in the JTLB are invalidated. The *Index* register is unused.

- For VTLB/FTLB -based MMU (*Config_{MT}*=4):

A TLBINV with the *Index* register set in VTLB range causes all matching entries in the VTLB to be invalidated.

A TLBINV with the *Index* register set in FTLB range causes all matching entries in the single corresponding FTLB set to be invalidated.

If TLB invalidate walk is implemented in software (*Config4_{IE}*=2), then software must do these steps to flush the entire MMU:

- one TLBINV instruction is executed with an index in VTLB range (invalidates all matching VTLB entries)
- a TLBINV instruction is executed for each FTLB set (invalidates all matching entries in FTLB set)

If TLB invalidate walk is implemented in hardware (*Config4_{IE}*=3), then software must do these steps to flush the entire MMU:

- one TLBINV instruction is executed (invalidates all matching entries in both FTLB & VTLB). In this case, *Index* is unused.

Restrictions:

The operation is **UNDEFINED** if the contents of the *Index* register are greater than or equal to the number of avail-

able TLB entries (For the case of $Config_{MT}=4$).

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Availability and Compatibility:

Implementation of the TLBINV instruction is optional. The implementation of this instruction is indicated by the IE field in *Config4*.

Implementation of *EntryHi_{EHINV}* field is required for implementation of TLBINV instruction.

Pre-Release 6, support for TLBINV is recommended for implementations supporting VTLB/FTLB type of MMU. Release 6 (and subsequent releases) support for TLBINV is required for implementations supporting VTLB/FTLB type of MMU.

Release 6: Processors that include a Block Address Translation (BAT) or Fixed Mapping (FM) MMU ($Config_{MT} = 2$ or 3), the operation of this instruction causes a Reserved Instruction exception (RI).

Operation:

```

if ( ConfigMT=1 or (ConfigMT=4 & Config4IE=2 & Index ≤ Config1MMU_SIZE-1) )
    startnum ← 0
    endnum ← Config1MMU_SIZE-1
endif
// treating VTLB and FTLB as one array
if (ConfigMT=4 & Config4IE=2 & Index > Config1MMU_SIZE-1)
    startnum ← start of selected FTLB set // implementation specific
    endnum ← end of selected FTLB set - 1 //implementation specific
endif

if (ConfigMT=4 & Config4IE=3)
    startnum ← 0
    endnum ← Config1MMU_SIZE-1 + ((Config4FTLBWays + 2) * Config4FTLBsets)
endif

for (i = startnum to endnum)
    if (TLB[i].ASID = EntryHiASID & TLB[i].G = 0)
        TLB[i].VPN2_invalid ← 1
    endif
endfor

```

Exceptions:

Coprocessor Unusable

31	26	25	24		6	5	0
COP0 010000	CO 1	0 000 0000 0000 0000 0000				TLBINVF 000100	
6	1	19				6	

Format: TLBINVF

MIPS32

Purpose: TLB Invalidate Flush

TLBINVF invalidates a set of TLB entries based on *Index* match. The virtual address and ASID are ignored in the entry match.

Implementation of the TLBINVF instruction is optional. The implementation of this instruction is indicated by the IE field in *Config4*.

Support for TLBINVF is recommend for implementations supporting VTLB/FTLB type of MMU.

Implementation of the *EntryHIEHINV* field is required for implementation of TLBINV and TLBINVF instructions.

Description:

On execution of the TLBINVF instruction, all entries within range of *Index* are invalidated.

Behavior of the TLBINVF instruction applies to all applicable TLB entries and is unaffected by the setting of the *Wired* register.

- For JTLB-based MMU (*Config_{MT}*=1):

TLBINVF causes all entries in the JTLB to be invalidated. *Index* is unused.

- For VTLB/FTLB-based MMU (*Config_{MT}*=4):

TLBINVF with *Index* in VTLB range causes all entries in the VTLB to be invalidated.

TLBINVF with *Index* in FTLB range causes all entries in the single corresponding set in the FTLB to be invalidated.

If TLB invalidate walk is implemented in your software (*Config_{4IE}*=2), then your software must do these steps to flush the entire MMU:

- one TLBINV instruction is executed with an index in VTLB range (invalidates all VTLB entries)
- a TLBINV instruction is executed for each FTLB set (invalidates all entries in FTLB set)

If TLB invalidate walk is implemented in hardware (*Config_{4IE}*=3), then software must do these steps to flush the entire MMU:

- one TLBINV instruction is executed (invalidates all entries in both FTLB & VTLB). In this case, *Index* is unused.

Restrictions:

The operation is **UNDEFINED** if the contents of the *Index* register are greater than or equal to the number of available TLB entries (*Config_{4IE}*=2).

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Availability and Compatibility:

Implementation of the TLBINV instruction is optional. The implementation of this instruction is indicated by the IE field in *Config4*.

Implementation of *EntryHl_{EHINV}* field is required for implementation of TLBINV instruction.

Pre-Release 6, support for TLBINV is recommended for implementations supporting VTLB/FTLB type of MMU. Release 6 (and subsequent releases) support for TLBINV is required for implementations supporting VTLB/FTLB type of MMU.

Release 6: Processors that include a Block Address Translation (BAT) or Fixed Mapping (FM) MMU ($\text{Config}_{\text{MT}} = 2$ or 3), the operation of this instruction causes a Reserved Instruction exception (RI).

Operation:

```

if ( ConfigMT=1 or (ConfigMT=4 & ConfigIE=2 & Index ≤ Config1MMU_SIZE-1) )
    startnum ← 0
    endnum ← Config1MMU_SIZE-1
endif
// treating VTLB and FTLB as one array
if (ConfigMT=4 & ConfigIE=2 & Index > Config1MMU_SIZE-1)
    startnum ← start of selected FTLB set //implementation specific
    endnum ← end of selected FTLB set - 1 //implementation specific
endif

if (ConfigMT=4 & ConfigIE=3)
    startnum ← 0
    endnum ← Config1MMU_SIZE-1 + ((Config4FTLBWays + 2) * Config4FTLBsets)
endif

for (i = startnum to endnum)
    TLB[i]VPN2_invalid ← 1
endfor

```

Exceptions:

Coprocessor Unusable

31	26	25	24		6	5	0
COP0 010000	CO 1	0 000 0000 0000 0000 0000				TLBP 001000	
6	1	19				6	

Format: TLBP**MIPS32****Purpose:** Probe TLB for Matching Entry

To find a matching entry in the TLB.

Description:

The *Index* register is loaded with the address of the TLB entry whose contents match the contents of the *EntryHi* register. If no TLB entry matches, the high-order bit of the *Index* register is set.

- In Release 1 of the Architecture, it is implementation dependent whether multiple TLB matches are detected on a TLBP. However, implementations are strongly encouraged to report multiple TLB matches only on a TLB write.
- In Release 2 of the Architecture, multiple TLB matches may only be reported on a TLB write.
- In Release 3 of the Architecture, multiple TLB matches may be reported on either TLB write or TLB probe.

Restrictions:

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Release 6: Processors that include a Block Address Translation (BAT) or Fixed Mapping (FM) MMU (Config_{MT} = 2 or 3), the operation of this instruction causes a Reserved Instruction exception (RI).

Operation:

```

Index ← 1 || UNPREDICTABLE31
for i in 0...TLBEntries-1
    if ((TLB[i]VPN2 and not (TLB[i]Mask)) =
        (EntryHiVPN2 and not (TLB[i]Mask))) and
        ((TLB[i]G = 1) or (TLB[i]ASID = EntryHiASID)) then
        Index ← i
    endif
endfor

```

Exceptions:

Coprocessor Unusable, Machine Check

31	26	25	24		6	5	0
COP0 010000	CO 1	0 000 0000 0000 0000 0000				TLBR 000001	
6	1	19				6	

Format: TLBR

MIPS32

Purpose: Read Indexed TLB Entry

To read an entry from the TLB.

Description:

The *EntryHi*, *EntryLo0*, *EntryLo1*, and *PageMask* registers are loaded with the contents of the TLB entry pointed to by the *Index* register.

- In Release 1 of the Architecture, it is implementation dependent whether multiple TLB matches are detected on a TLBR. However, implementations are strongly encouraged to report multiple TLB matches only on a TLB write.
- In Release 2 of the Architecture, multiple TLB matches may only be reported on a TLB write.
- In Release 3 of the Architecture, multiple TLB matches may be detected on a TLBR.

In an implementation supporting TLB entry invalidation (*Config4_{IE}* = 2 or *Config4_{IE}* = 3), reading an invalidated TLB entry causes 0 to be written to *EntryHi*, *EntryLo0*, *EntryLo1* registers and the *PageMask_{MASK}* register field.

The value written to the *EntryHi*, *EntryLo0*, and *EntryLo1* registers may be different from the original written value to the TLB via these registers in that:

- The value returned in the *VPN2* field of the *EntryHi* register may have those bits set to zero corresponding to the one bits in the Mask field of the TLB entry (the least-significant bit of *VPN2* corresponds to the least-significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed after a TLB entry is written and then read.
- The value returned in the *PFN* field of the *EntryLo0* and *EntryLo1* registers may have those bits set to zero corresponding to the one bits in the Mask field of the TLB entry (the least significant bit of *PFN* corresponds to the least significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed after a TLB entry is written and then read.
- The value returned in the *G* bit in both the *EntryLo0* and *EntryLo1* registers comes from the single *G* bit in the TLB entry. Recall that this bit was set from the logical AND of the two *G* bits in *EntryLo0* and *EntryLo1* when the TLB was written.

Restrictions:

The operation is **UNDEFINED** if the contents of the Index register are greater than or equal to the number of TLB entries in the processor.

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Release 6: Processors that include a Block Address Translation (BAT) or Fixed Mapping (FM) MMU (*Config_{MT}* = 2 or 3), the operation of this instruction causes a Reserved Instruction exception (RI).

Operation:

$i \leftarrow \text{Index}$

```

if i > (TLBEntries - 1) then
    UNDEFINED
endif
if ( (Config4IE = 2 or Config4IE = 3) and TLB[i]VPN2_invalid = 1) then

6	1	19				6	

Format: TLBWI

MIPS32

Purpose: Write Indexed TLB Entry

To write or invalidate a TLB entry indexed by the *Index* register.

Description:

If $Config4_{IE} < 2$ or $EntryHi_{EHINV} = 0$:

The TLB entry pointed to by the Index register is written from the contents of the *EntryHi*, *EntryLo0*, *EntryLo1*, and *PageMask* registers. It is implementation dependent whether multiple TLB matches are detected on a TLBWI. In such an instance, a Machine Check Exception is signaled.

In Release 2 of the Architecture, multiple TLB matches may only be reported on a TLB write. The information written to the TLB entry may be different from that in the *EntryHi*, *EntryLo0*, and *EntryLo1* registers, in that:

- The value written to the VPN2 field of the TLB entry may have those bits set to zero corresponding to the one bits in the Mask field of the *PageMask* register (the least significant bit of VPN2 corresponds to the least significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed during a TLB write.
- The value written to the PFN0 and PFN1 fields of the TLB entry may have those bits set to zero corresponding to the one bits in the Mask field of *PageMask* register (the least significant bit of PFN corresponds to the least significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed during a TLB write.
- The single G bit in the TLB entry is set from the logical AND of the *G* bits in the *EntryLo0* and *EntryLo1* registers.

If $Config4_{IE} > 1$ and $EntryHi_{EHINV} = 1$:

The TLB entry pointed to by the Index register has its VPN2 field marked as invalid. This causes the entry to be ignored on TLB matches for memory accesses. No Machine Check is generated.

Restrictions:

The operation is **UNDEFINED** if the contents of the Index register are greater than or equal to the number of TLB entries in the processor.

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Release 6: Processors that include a Block Address Translation (BAT) or Fixed Mapping (FM) MMU ($Config_{MT} = 2$ or 3), the operation of this instruction causes a Reserved Instruction exception (RI).

Operation:

```

i ← Index
if (Config4IE = 2 or Config4IE = 3) then
    TLB[i]VPN2_invalid ← 0
    if ( EntryHiEHINV=1 ) then

```

```

        TLB[i]_VPN2_invalid ← 1
        break
    endif
endif

The TLB entry pointed to by the *Random* register is written from the contents of the *EntryHi*, *EntryLo0*, *EntryLo1*, and *PageMask* registers. It is implementation dependent whether multiple TLB matches are detected on a TLBWR. In such an instance, a Machine Check Exception is signaled.

In Release 2 of the Architecture, multiple TLB matches may only be reported on a TLB write. The information written to the TLB entry may be different from that in the *EntryHi*, *EntryLo0*, and *EntryLo1* registers, in that:

- The value written to the VPN2 field of the TLB entry may have those bits set to zero corresponding to the one bits in the Mask field of the *PageMask* register (the least significant bit of VPN2 corresponds to the least significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed during a TLB write.
- The value written to the PFN0 and PFN1 fields of the TLB entry may have those bits set to zero corresponding to the one bits in the Mask field of *PageMask* register (the least significant bit of PFN corresponds to the least significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed during a TLB write.
- The single G bit in the TLB entry is set from the logical AND of the G bits in the *EntryLo0* and *EntryLo1* registers.

Restrictions:

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Release 6: Processors that include a Block Address Translation (BAT) or Fixed Mapping (FM) MMU (Config_{MT} = 2 or 3), the operation of this instruction causes a Reserved Instruction exception (RI).

Operation:

```

i ← Random
if (Config4IE = 2 or Config4IE = 3) then
    TLB[i]VPN2_invalid ← 0
endif
TLB[i]Mask ← PageMaskMask
TLB[i]VPN2 ← EntryHiVPN2 and not PageMaskMask # Implementation dependent
TLB[i]ASID ← EntryHiASID
TLB[i]G ← EntryLo1G and EntryLo0G
TLB[i]PFN1 ← EntryLo1PFN and not PageMaskMask # Implementation dependent
TLB[i]C1 ← EntryLo1C
TLB[i]D1 ← EntryLo1D
TLB[i]V1 ← EntryLo1V
TLB[i]PFN0 ← EntryLo0PFN and not PageMaskMask # Implementation dependent
TLB[i]C0 ← EntryLo0C

```

$$\text{TLB}[i]_{\text{D0}} \leftarrow \text{EntryLo0}_{\text{D}}$$
$$\text{TLB}[i]_{\text{V0}} \leftarrow \text{EntryLo0}_{\text{V}}$$
Exceptions:

Coproprocessor Unusable

Machine Check

Format: TLT *rs*, *rt*

MIPS32

Purpose: Trap if Less Than

To compare GPRs and do a conditional trap.

Description: if GPR[*rs*] < GPR[*rt*] then Trap

Compare the contents of GPR *rs* and GPR *rt* as signed integers. If GPR *rs* is less than GPR *rt*, then take a Trap exception.

The contents of the *code* field are ignored by hardware and may be used to encode information for system software. To retrieve the information, system software must load the instruction word from memory.

Restrictions:

None

Operation:

```
if GPR[rs] < GPR[rt] then
    SignalException(Trap)
endif
```

Exceptions:

Trap

Format: TLTI rs, immediate

MIPS32, removed in Release 6

Purpose: Trap if Less Than Immediate

To compare a GPR to a constant and do a conditional trap.

Description: if GPR[rs] < immediate then Trap

Compare the contents of GPR *rs* and the 16-bit signed *immediate* as signed integers. If GPR *rs* is less than *immediate*, then take a Trap exception.

Restrictions:

None

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```
if GPR[rs] < sign_extend(immediate) then
    SignalException(Trap)
endif
```

Exceptions:

Trap

Format: TLTIU rs, immediate

MIPS32, removed in Release 6

Purpose: Trap if Less Than Immediate Unsigned

To compare a GPR to a constant and do a conditional trap.

Description: if GPR[rs] < immediate then Trap

Compare the contents of GPR *rs* and the 16-bit sign-extended *immediate* as unsigned integers. If GPR *rs* is less than *immediate*, then take a Trap exception.

Because the 16-bit *immediate* is sign-extended before comparison, the instruction can represent the smallest or largest unsigned numbers. The representable values are at the minimum [0, 32767] or maximum [max_unsigned-32767, max_unsigned] end of the unsigned range.

Restrictions:

None

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```
if (0 || GPR[rs]) < (0 || sign_extend(immediate)) then
    SignalException(Trap)
endif
```

Exceptions:

Trap

Format: TLTU *rs*, *rt*

MIPS32

Purpose: Trap if Less Than Unsigned

To compare GPRs and do a conditional trap.

Description: if GPR[*rs*] < GPR[*rt*] then Trap

Compare the contents of GPR *rs* and GPR *rt* as unsigned integers. If GPR *rs* is less than GPR *rt*, then take a Trap exception.

The contents of the *code* field are ignored by hardware and may be used to encode information for system software. To retrieve the information, system software must load the instruction word from memory.

Restrictions:

None

Operation:

```
if (0 || GPR[rs]) < (0 || GPR[rt]) then
    SignalException(Trap)
endif
```

Exceptions:

Trap

Format: TNE *rs*, *rt*

MIPS32

Purpose: Trap if Not Equal

To compare GPRs and do a conditional trap.

Description: if GPR[*rs*] \neq GPR[*rt*] then Trap

Compare the contents of GPR *rs* and GPR *rt* as signed integers. If GPR *rs* is not equal to GPR *rt*, then take a Trap exception.

The contents of the *code* field are ignored by hardware and may be used to encode information for system software. To retrieve the information, system software must load the instruction word from memory.

Restrictions:

None

Operation:

```

if GPR[rs]  $\neq$  GPR[rt] then
    SignalException(Trap)
endif

```

Exceptions:

Trap

31	26	25	21	20	16	15	0
REGIMM 000001			rs		TNEI 01110		immediate
6			5		5		16

Format: TNEI rs, immediate

MIPS32, removed in Release 6

Purpose: Trap if Not Equal Immediate

To compare a GPR to a constant and do a conditional trap.

Description: if `GPR[rs] ≠ immediate` then Trap

Compare the contents of GPR *rs* and the 16-bit signed *immediate* as signed integers. If GPR *rs* is not equal to *immediate*, then take a Trap exception.

Restrictions:

None

Availability and Compatibility:

This instruction has been removed in Release 6.

Operation:

```
if GPR[rs] ≠ sign_extend(immediate) then
    SignalException(Trap)
endif
```

Exceptions:

Trap

31	26	25	21	20	16	15	11	10	6	5	0
COP1 010001	fmt					0 00000	fs		fd		TRUNC.L 001001
6	5					5	5		5		6

Format: TRUNC.L.fmt
 TRUNC.L.S fd, fs
 TRUNC.L.D fd, fs

MIPS32 Release 2
MIPS32 Release 2

Purpose: Floating Point Truncate to Long Fixed Point

To convert an FP value to 64-bit fixed point, rounding toward zero.

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

The value in FPR *fs*, in format *fmt*, is converted to a value in 64-bit long-fixed point format and rounded toward zero (rounding mode 1). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{63} to $2^{63}-1$, the result cannot be represented correctly and an IEEE Invalid Operation condition exists. In this case the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, $2^{63}-1$, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs: *fs* for type *fmt* and *fd* for long fixed point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in the *FR*=0 32-bit FPU register model; it is predictable if executing on a 64-bit FPU in the *FR*=1 mode, but not with *FR*=0, and not on a 32-bit FPU.

Operation:

$\text{StoreFPR}(fd, L, \text{ConvertFmt}(\text{ValueFPR}(fs, fmt), fmt, L))$

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation, Invalid Operation, Inexact

31	26	25	21	20	16	15	11	10	6	5	0

 TRUNC.W.S fd, fs
 TRUNC.W.D fd, fs

MIPS32
MIPS32

Purpose: Floating Point Truncate to Word Fixed Point

To convert an FP value to 32-bit fixed point, rounding toward zero.

Description: $FPR[fd] \leftarrow \text{convert_and_round}(FPR[fs])$

The value in FPR *fs*, in format *fmt*, is converted to a value in 32-bit word fixed point format using rounding toward zero (rounding mode 1). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{31} to $2^{31}-1$, the result cannot be represented correctly and an IEEE Invalid Operation condition exists. In this case the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, $2^{31}-1$, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs: *fs* for type *fmt* and *fd* for word fixed point. If the fields are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

`StoreFPR(fd, W, ConvertFmt(ValueFPR(fs, fmt), fmt, W))`

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Invalid Operation, Unimplemented Operation

31	26	25	24		6	5	0
COP0 010000	CO 1	Implementation-dependent code				WAIT 100000	
6	1	19				6	

Format: WAIT

MIPS32

Purpose: Enter Standby Mode

Wait for Event

Description:

The WAIT instruction performs an implementation-dependent operation, involving a lower power mode. Software may use the code bits of the instruction to communicate additional information to the processor. The processor may use this information as control for the lower power mode. A value of zero for code bits is the default and must be valid in all implementations.

The WAIT instruction is implemented by stalling the pipeline at the completion of the instruction and entering a lower power mode. The pipeline is restarted when an external event, such as an interrupt or external request occurs, and execution continues with the instruction following the WAIT instruction. It is implementation-dependent whether the pipeline restarts when a non-enabled interrupt is requested. In this case, software must poll for the cause of the restart. The assertion of any reset or NMI must restart the pipeline and the corresponding exception must be taken.

If the pipeline restarts as the result of an enabled interrupt, that interrupt is taken between the WAIT instruction and the following instruction (EPC for the interrupt points at the instruction following the WAIT instruction).

Restrictions:

Pre-Release 6: The operation of the processor is **UNDEFINED** if a WAIT instruction is executed in the delay slot of a branch or jump instruction.

Release 6 implementations are required to signal a Reserved Instruction Exception if a WAIT instruction is encountered in the delay slot or forbidden slot of a branch or jump instruction.

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Operation:

```
I: Enter implementation dependent lower power mode
I+1:/* Potential interrupt taken here */
```

Exceptions:

Coprocessor Unusable Exception

31	26	25	21	20	16	15	11	10	0
COP0 0100 00		WRPGPR 01 110		rt	rd		0 000 0000 0000		
6		5		5	5		11		

Format: WRPGPR rd, rt

MIPS32 Release 2

Purpose: Write to GPR in Previous Shadow Set

To move the contents of a current GPR to a GPR in the previous shadow set.

Description: $SGPR[SRSCtl_{pss}, rd] \leftarrow GPR[rt]$

The contents of the current GPR *rt* is moved to the shadow GPR register specified by *SRSCtl_{pss}* (signifying the previous shadow set number) and *rd* (specifying the register number within that set).

Restrictions:

In implementations prior to Release 2 of the Architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

$SGPR[SRSCtl_{pss}, rd] \leftarrow GPR[rt]$

Exceptions:

Coprocessor Unusable

Reserved Instruction

Format: WSBH rd, rt

MIPS32 Release 2

Purpose: Word Swap Bytes Within Halfwords

To swap the bytes within each halfword of GPR *rt* and store the value into GPR *rd*.

Description: $\text{GPR}[rd] \leftarrow \text{SwapBytesWithinHalfwords}(\text{GPR}[rt])$

Within each halfword of GPR *rt* the bytes are swapped, and stored in GPR *rd*.

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

$$\text{GPR}[rd] \leftarrow \text{GPR}[r]_{23..16} \parallel \text{GPR}[r]_{31..24} \parallel \text{GPR}[r]_{7..0} \parallel \text{GPR}[r]_{15..8}$$

Exceptions:

Reserved Instruction

Programming Notes:

The WSBH instruction can be used to convert halfword and word data of one endianness to another endianness. The endianness of a word value can be converted using the following sequence:

```
lw    t0, 0(a1)           /* Read word value */
wsbh  t0, t0              /* Convert endiannes of the halfwords */
rotr  t0, t0, 16          /* Swap the halfwords within the words */
```

Combined with SEH and SRA, two contiguous halfwords can be loaded from memory, have their endianness converted, and be sign-extended into two word values in four instructions. For example:

```
lw    t0, 0(a1)           /* Read two contiguous halfwords */
wsbh  t0, t0              /* Convert endiannes of the halfwords */
seh   t1, t0              /* t1 = lower halfword sign-extended to word */
sra   t0, t0, 16          /* t0 = upper halfword sign-extended to word */
```

Zero-extended words can be created by changing the SEH and SRA instructions to ANDI and SRL instructions, respectively.

31	26	25	21	20	16	15	11	10	6	5	0	
SPECIAL 000000			rs		rt		rd		0 00000		XOR 100110	
6			5		5		5		5		6	

Format: XOR *rd*, *rs*, *rt*

MIPS32

Purpose: Exclusive OR

To do a bitwise logical Exclusive OR.

Description: $GPR[rd] \leftarrow GPR[rs] \text{ XOR } GPR[rt]$

Combine the contents of GPR *rs* and GPR *rt* in a bitwise logical Exclusive OR operation and place the result into GPR *rd*.

Restrictions:

None

Operation:

$GPR[rd] \leftarrow GPR[rs] \text{ xor } GPR[rt]$

Exceptions:

None

Format: XORI *rt*, *rs*, *immediate*

MIPS32

Purpose: Exclusive OR Immediate

To do a bitwise logical Exclusive OR with a constant.

Description: $GPR[rt] \leftarrow GPR[rs] \text{ XOR } immediate$

Combine the contents of GPR *rs* and the 16-bit zero-extended *immediate* in a bitwise logical Exclusive OR operation and place the result into GPR *rt*.

Restrictions:

None

Operation:

$GPR[rt] \leftarrow GPR[rs] \text{ xor } zero_extend(immediate)$

Exceptions:

None

Instruction Bit Encodings

A.1 Instruction Encodings and Instruction Classes

Instruction encodings are presented in this section; field names are printed here and throughout the book in *italics*.

When encoding an instruction, the primary *opcode* field is encoded first. Most *opcode* values completely specify an instruction that has an *immediate* value or offset.

Opcode values that do not specify an instruction instead specify an instruction class. Instructions within a class are further specified by values in other fields. For instance, *opcode* REGIMM specifies the *immediate* instruction class, which includes conditional branch and trap *immediate* instructions.

A.2 Instruction Bit Encoding Tables

This section provides various bit encoding tables for the instructions of the MIPS32® ISA.

Figure A.1 shows a sample encoding table and the instruction *opcode* field this table encodes. Bits 31..29 of the *opcode* field are listed in the leftmost columns of the table. Bits 28..26 of the *opcode* field are listed along the topmost rows of the table. Both decimal and binary values are given, with the first three bits designating the row, and the last three bits designating the column.

An instruction's encoding is found at the intersection of a row (bits 31..29) and column (bits 28..26) value. For instance, the *opcode* value for the instruction labeled EX1 is 33 (decimal, row and column), or 011011 (binary). Similarly, the *opcode* value for EX2 is 64 (decimal), or 110100 (binary).

Release 6 introduces additional nomenclature to the opcode tables for Release 6 instructions. For new instructions, bits 31:26 are generically named POPXY where X is the row number, and Y is the column number. This convention is extended to sub-opcode tables, except bits 5:0 are generically named SOPXY, where X is the row number, and Y is the column number. This naming convention is applied where a specific encoded value may be shared by multiple instructions.

Figure A.1 Sample Bit Encoding Table

Tables A.2 through A.20 describe the encoding used for the MIPS32 ISA. Table A.1 describes the meaning of the symbols used in the tables.

Table A.1 Symbols Used in the Instruction Encoding Tables

Symbol	Meaning
*	Operation or field codes marked with this symbol are reserved for future use. Executing such an instruction must cause a Reserved Instruction Exception. Note: Some instruction encodings are assigned to coprocessors (as indicated by COP0 or COP1 in the encoding table titles). For such instruction encodings, the Coprocessor Unavailable exception takes priority over the Reserved Instruction exception.
no marking	Many instructions are optional, or available only in certain configurations. As of Release 6, if a table entry would be empty in a particular configuration, then implementations are required to signal a Reserved Instruction exception when executed. Pre-Release 6 signalling a reserved instruction was not necessarily required, hence symbols such as * ⊥ ∇ Δ which indicate when such signalling is required or present, and when not. In other words, as of Release 6 full instruction decoding, including detection of unused instructions, is assumed as the default.
δ	(Also <i>italic</i> field name.) Operation or field codes marked with this symbol denotes a field class. The instruction word must be further decoded by examining additional tables that show values for another instruction field.
β	Operation or field codes marked with this symbol represent a valid encoding for a higher-order MIPS ISA level or a new revision of the Architecture. Executing such an instruction must cause a Reserved Instruction Exception.

Table A.1 Symbols Used in the Instruction Encoding Tables (Continued)

Symbol	Meaning
∇	Operation or field codes marked with this symbol represent instructions which were only legal if 64-bit operations were enabled on implementations of Release 1 of the Architecture. In Release 2 of the architecture, operation or field codes marked with this symbol represent instructions which are legal if 64-bit floating point operations are enabled. In other cases, executing such an instruction must cause a Reserved Instruction Exception (non-coprocessor encodings or coprocessor instruction encodings for a coprocessor to which access is allowed) or a Coprocessor Unusable Exception (coprocessor instruction encodings for a coprocessor to which access is not allowed).
Δ	Instructions formerly marked ∇ in some earlier versions of manuals, corrected and marked Δ in revision 5.03. Legal on MIPS64r1 but not MIPS32r1; in release 2 and above, legal in both MIPS64 and MIPS32, in particular even when running in “32-bit FPU Register File mode”, FR=0, as well as FR=1.
θ	Operation or field codes marked with this symbol are available to licensed MIPS partners. To avoid multiple conflicting instruction definitions, MIPS Technologies will assist the partner in selecting appropriate encodings if requested by the partner. The partner is not required to consult with MIPS Technologies when one of these encodings is used. If no instruction is encoded with this value, executing such an instruction must cause a Reserved Instruction Exception (<i>SPECIAL2</i> encodings or coprocessor instruction encodings for a coprocessor to which access is allowed) or a Coprocessor Unusable Exception (coprocessor instruction encodings for a coprocessor to which access is not allowed).
θ^*	Release 6 reserves the <i>SPECIAL2</i> encodings. pre-MIPS32 Release 2 the <i>SPECIAL2</i> encodings were available for customer use as UDIs. Otherwise like θ above.
σ	Field codes marked with this symbol represent an EJTAG support instruction and implementation of this encoding is optional for each implementation. If the encoding is not implemented, executing such an instruction must cause a Reserved Instruction Exception. If the encoding is implemented, it must match the instruction encoding as shown in the table.
ε	Operation or field codes marked with this symbol are reserved for MIPS optional Module or Application Specific Extensions. If the Module/ASE is not implemented, executing such an instruction must cause a Reserved Instruction Exception.
ϕ	Operation or field codes marked with this symbol are obsolete and will be removed from a future revision of the MIPS32 ISA. Software should avoid using these operation or field codes.
\oplus	Operation or field codes marked with this symbol are valid for Release 2 implementations of the architecture. Executing such an instruction in a Release 1 implementation must cause a Reserved Instruction Exception.
6N	Instruction added by Release 6. “N” for “new”.
6Nm	New Release 6 encoding for a pre-Release 6 instruction that has been moved. “Nm” for “New (moved)”

Table A.1 Symbols Used in the Instruction Encoding Tables (Continued)

Symbol	Meaning	
6Rm	pre-Release 6 instruction encoding moved in Release 6. “Rm” for “Removed (moved elsewhere)”.	6Rm and 6R instructions signal a Reserved Instruction Exception when executed by a Release 6 implementation. If the encoding has been used for a new instruction or coprocessor, the unusable exception takes priority.
6R	pre-Release 6 instruction encoding removed by Release 6. “R” for “Removed”.	

Table A.2 MIPS32 Encoding of the Opcode Field

opcode		bits 28..26

1. Pre-Release 6 instruction LUI is a special case of Release 6 instruction AUI.
2. Architecture Release 1, the COP1X opcode was called COP3, and was available as another user-available coprocessor. Architecture Release 2, a full 64-bit floating point unit is available with 32-bit CPUs, and the COP1X opcode is reserved for that purpose on all Release 2 CPUs. 32-bit implementations of Release 1 of the architecture are strongly discouraged from using this opcode for a user-available coprocessor as doing so limits the potential for an upgrade path for the FPU.
3. Architecture Release 2 added the SPECIAL3 opcode. Implementations of Release 1 of the Architecture signaled a Reserved Instruction Exception for this opcode.

Table A.3 MIPS32 SPECIAL Opcode Encoding of Function Field

function		bits 2..0							
		0	1	2	3	4	5	6	7

7	111	β	*	β	β	β	*	β	β

- Specific encodings of the *rt*, *rd*, and *sa* fields are used to distinguish among the SLL, NOP, SSNOP, EHB and PAUSE functions. Release 6 makes SSNOP equivalent to NOP.
- Specific encodings of the *hint* field are used to distinguish JR from JR.HB and JALR from JALR.HB
- Release 6 removes JR and JR.HB. JALR with *rd*=0 provides functionality equivalent to JR. JALR.HB with *rd*=0 provides functionality equivalent to JR.HB. Assemblers should produce the new instruction when encountering the old mnemonic.
- Specific encodings of the *sa* field are used to distinguish pre-Release 6 and Release 6 integer multiply and divide instructions. See Table A.22 on page 446, which shows that the encodings do not conflict. The pre-Release 6 divide instructions signal Reserved Instruction exception on Release 6. Note that the same mnemonics are used for pre-Release 6 divide instructions that return both quotient and remainder, and Release 6 divide instructions that return only quotient, with separate MOD instructions for the remainder.

Table A.4 MIPS32 REGIMM Encoding of *rt* Field

rt		bits 18..16							
		0	1	2	3	4	5	6	7

1. Format type *L* is legal only if 64-bit floating point operations are enabled.
2. Release 6 introduces the CMP.condn.fmt instruction family, where .fmt=S or D, 32 or 64 bit floating point. However, .S and .D for CMP.condn.fmt are encoded as .W 10100 and .L 10101 in the “standard” format. The conditions tested are encoded the same way for pre-Release 6 C.cond.fmt and Release 6 CMP.cond.fmt, except that Release 6 adds new conditions not present in C.cond.fmt. Release 6, however, has changed the recommended mnemonics for the CMP.condn.fmt to be consistent with the IEEE standard rather than pre-Release 6. See the table in the description of CMP.cond.fmt in Volume II of the MIPS Architecture Reference Manual, which shows the correspondence between pre-Release 6 C.cond.fmt, Release 6 CMP.cond.fmt, and MSA FC*.fmt / FS*.fmt floating point comparisons.

- Release 6 removes format type PS (paired single). MSA (MIPS SIMD Architecture) may be used instead.
- Release 6 removes all pre-Release 6 COP1X instructions, of the form 010011 - COP1X.PS, non-fused FP multiply adds, and indexed and unaligned loads, stores, and prefetches.

A.3 Floating Point Unit Instruction Format Encodings

Instruction format encodings for the floating point unit are presented in this section. This information is a tabular presentation of the encodings described in tables ranging from Table A.13 to Table A.20 above.

Table A.21 Floating Point Unit Instruction Format Encodings

<i>fmt</i> field (bits 25..21 of COP1 opcode)		<i>fmt3</i> field (bits 2..0 of COP1X opcode)					
Decimal	Hex	Decimal	Hex	Mnemonic	Name	Bit Width	Data Type
0..15	00..0F	—	—	Used to encode Coprocessor 1 interface instructions (MFC1, CTC1, etc.). Not used for format encoding.			
16	10	0	0	S	Single	32	Floating Point
				See note below: Release 6 CMP.condn.S/D encoded as W/L.			
17	11	1	1	D	Double	64	Floating Point
				See note below: Release 6 CMP.condn.S/D encoded as W/L.			
18..19	12..13	2..3	2..3	Reserved for future use by the architecture.			
20	14	4	4	W	Word	32	Fixed Point
				See note below: Release 6 CMP.condn.S/D encoded as W/L.			
21	15	5	5	L	Long	64	Fixed Point
				See note below: Release 6 CMP.condn.S/D encoded as W/L.			
22	16	6	6	PS	Paired Single	2 × 32	Floating Point
				Release 6 removes the PS format, and reserves it for future use			
23	17	7	7	Reserved for future use by the architecture.			
24..31	18..1F	—	—	Reserved for future use by the architecture. Not available for <i>fmt3</i> encoding.			

Note: Release 6 CMP.condn.S/D encoded as W/L: as described in Table A.16 on page 442, “MIPS32 COP1 Encoding of Function Field When rs=W or L” on page 442, Release 6 uses certain instruction encodings with the *rs (fmt)* field equal to 11000 (W) or 11001 (L) to represent S and D respectively, for the instruction family CMP.condn.fmt.

A.4 Release 6 Instruction Encodings

Release 6 adds several new instructions, removes several old instructions, and changes the encodings of several pre-Release 6 instructions. In many cases, the old encodings for instructions moved or removed are required to signal the Reserved Instruction on Release 6, so that uses of old instructions can be trapped, and emulated or warned about; but in several cases the old encodings have been reused for new Release 6 instructions.

These instruction encoding changes are indicated in the tables above. Release 6 new instructions are superscripted 6N; Release 6 removed instructions are superscripted 6R; Release 6 instructions that have been moved are marked 6Rm at the pre-Release 6 encoding that they are moved from, and 6Nm at the new Release 6 encoding that it is moved to. Encoding table cells that contain both a non-Release 6 instruction and a Release 6 instruction superscripted 6N or 6Nm indicate a possible conflict, although in many cases footnotes indicate that other fields allow the distinction to be made.

The tables below show the further decoding in Release 6 for field classes (instruction encoding families) indicated in other tables.

Instruction encodings are also illustrated in the instruction descriptions in Volume II. Those encodings are authoritative. The instruction encoding tables in this section, above, based on bitfields, are illustrative, since they cannot completely indicate the new tighter encodings.

MUL/DIV family encodings: Table A.22 below shows the Release 6 integer family of multiply and divide instructions encodings, as well as the pre-Release 6 instructions they replace. The Release 6 and pre-Release 6 instructions share the same primary opcode, bits 31-26 = 000000, and share the function code, bits 5-0, with their pre-Release 6 counterparts, but are distinguished by bits 10-6 of the instruction. The pre-Release 6 instructions signal a Reserved Instruction exception on Release 6 implementations.

However, the instruction names collide: pre-Release 6 and Release 6 DIV, DIVU, DDIV, DDIVU are actually distinct instructions, although they share the same mnemonics. The pre-Release 6 instructions produce two results, both quotient and remainder in the HI/LO register pair, while the Release 6 DIV instruction produce only a single result, the quotient. It is possible to distinguish the conflicting instructions in assembly by looking at how many register operands the instructions have, two versus three.

As of Release 6, all of pre-Release 6 instruction encodings that are removed are required to signal the reserved instruction exception, as are all in the vicinity 000000.xxxxx.xxxxx.aaaaa.011xxx, i.e. all with the primary opcodes and function codes listed in Table A.22, with the exception of the aaaaa field values 00010 and 00011 for the new instructions.

Table A.22 Release 6 MUL/DIV encodings

pre-Release 6 removed ~~struck through~~
00000.rs.rt.rd.aaaaa.function6

function bits 5-0	aaaaa, bits 10-6		
	00000 and rd = 00000 (bits 15-11)	00010	00011
011 000	MULT ^{6R}	MUL ^{6N}	MUH ^{6N}
011 001	MULTU ^{6R}	MULU ^{6N}	MUHU ^{6N}
011 010	DIV ^{6R}	DIV ^{6N}	MOD ^{6N}
011 011	DIVU ^{6R}	DIVU ^{6N}	MODU ^{6N}
011 100	β^{6R}	β^{6N}	β^{6N}
011 101	β^{6R}	β^{6N}	β^{6N}
011 110	β^{6R}	β^{6N}	β^{6N}
011 111	β^{6R}	β^{6N}	β^{6N}

PC-relative family encodings: Table A.23 and Table A.24 present the PC-relative family of instruction encodings. Table A.23 in traditional form, Table A.24 in the bitstring form that clearly shows the immediate varying from 19 bits to 16 bits.

Table A.23 Release 6 PC-relative family encoding

111011.rs.TTTT.immediate

rs		bits 18-16							
bits 20-19		0	1	2	3	4	5	6	7
		000	001	010	011	100	101	110	111
0	00	ADDIUP ^{6N} immediate							
1	01	LWP ^{6N} immediate							
2	10	β^{6N}							
3	11	β^{6N}				reserved (RI)		AUIP ^{6N} immediate	ALUIP ^{6N} immediate

Table A.24 Release 6 PC-relative family encoding bitstrings

111011.rs.*

encoding	instruction
111011.rs.00.<-----immediate>	ADDIUPC ^{6N}
111011.rs.01.<----off19>	LWPC ^{6N}
111011.rs.10.<----off19>	β^{6N}
111011.rs.110.<---off18>	β^{6N}
111011.rs.1110.<---imm17>	reserved, signal RI ^{6N}
111011.rs.11110.<--immediate>	AUIPC ^{6N}
111011.rs.11111.<--immediate>	ALUIPC ^{6N}

B*C compact branch and jump encodings: In several cases Release 6 uses much tighter instruction encodings than previous releases of the MIPS architecture, reducing redundancy, to allow more instructions to be encoded. Instead of purely looking at bitfields, Release 6 defines encodings that compare different bitfields: e.g. the encoding 010110.rs.rt.offset16 is BGEC if neither rs nor rt are 00000 and rs is not equal to rt, but is BGEZC if rs is the same as rt, and is BLEZC if rs is 00000 and rt is not. (The encoding with rt 00000 and arbitrary rs is the pre-Release 6 instruction BLEZL.rs.00000.offset16, a branch likely instruction which is removed by Release 6, and whose encoding is required to signal the Reserved Instruction exception.)

This tight instruction encoding motivates the bitstring and constraints notation for Release 6 instruction encodings

BLEZC rt	010110.00000.rt.offset16,	rt!=0
BGEZC rt	010110.rs=rt.rt.offset16, rs!=0,	rt!=0, rs=rt
BGEC rs,rt	10110.rs.rt.offset16, rs!=0,	rt!=0, rs!=rt
BLEZL rt	010110.00000.rt.offset16,	rs=0

and the equivalent constraints indicated in the instruction encoding diagrams for the instruction descriptions in Volume II. Table A.25 below shows the B*C compact branch encodings, which use constraints such as RS = RT. pre-Release 6 encodings that are removed by Release 6 are shaded darkly, while the remaining redundant encodings are shaded lightly or stippled.

Note: Pre-Release 6 instructions BLEZL, BGTZL, BLEZ, and BGTZ do not conflict with the new Release 6 instructions they are tightly packed with in the encoding tables, but the ADDI, DADDI, LWC2, SWC2, LDC2 and SDC2 truly conflict.

Table A.25 B*C compact branch encodings

Primary Opcode	Constraints involving rs and rt fields			
	rs/rt ₀ /NZ		NZ _{rs} =/</> NZ _{rt}

Revision History

Revision	Date	Description
0.90	November 1, 2000	Internal review copy of reorganized and updated architecture documentation.
0.91	November 15, 2000	Internal review copy of reorganized and updated architecture documentation.
0.92	December 15, 2000	Changes in this revision: <ul style="list-style-type: none"> • Correct sign in description of MSUBU. • Update JR and JALR instructions to reflect the changes required by MIPS16.
0.95	March 12, 2001	Update for second external review release
1.00	August 29, 2002	Update based on all review feedback: <ul style="list-style-type: none"> • Add missing optional select field syntax in mtc0/mfc0 instruction descriptions. • Correct the PREF instruction description to acknowledge that the Prepare-ForStore function does, in fact, modify architectural state. • To provide additional flexibility for Coprocessor 2 implementations, extend the <i>sel</i> field for DMFC0, DMTC0, MFC0, and MTC0 to be 8 bits. • Update the PREF instruction to note that it may not update the state of a locked cache line. • Remove obviously incorrect documentation in DIV and DIVU with regard to putting smaller numbers in register <i>rt</i>. • Fix the description for MFC2 to reflect data movement from the coprocessor 2 register to the GPR, rather than the other way around. • Correct the pseudo code for LDC1, LDC2, SDC1, and SDC2 for a MIPS32 implementation to show the required word swapping. • Indicate that the operation of the CACHE instruction is UNPREDICTABLE if the cache line containing the instruction is the target of an invalidate or writeback invalidate. • Indicate that an Index Load Tag or Index Store Tag operation of the CACHE instruction must not cause a cache error exception. • Make the entire right half of the MFC2, MTC2, CFC2, CTC2, DMFC2, and DMTC2 instructions implementation dependent, thereby acknowledging that these fields can be used in any way by a Coprocessor 2 implementation. • Clean up the definitions of LL, SC, LLD, and SCD. • Add a warning that software should not use non-zero values of the stype field of the SYNC instruction. • Update the compatibility and subsetting rules to capture the current requirements.

Revision	Date	Description
1.90	September 1, 2002	<p>Merge the MIPS Architecture Release 2 changes in for the first release of a Release 2 processor. Changes in this revision include:</p> <ul style="list-style-type: none"> • All new Release 2 instructions have been included: DI, EHB, EI, EXT, INS, JALR.HB, JR.HB, MFHC1, MFHC2, MTHC1, MTHC2, RDHWR, RDP-GPR, ROTR, ROTRV, SEB, SEH, SYNCI, WRPGPR, WSBH. • The following instruction definitions changed to reflect Release 2 of the Architecture: DERET, ERET, JAL, JALR, JR, SRL, SRLV • With support for 64-bit FPUs on 32-bit CPUs in Release 2, all floating point instructions that were previously implemented by MIPS64 processors have been modified to reflect support on either MIPS32 or MIPS64 processors in Release 2. • All pseudo-code functions have been updated, and the Are64BitFPOperationsEnabled function was added. • Update the instruction encoding tables for Release 2.
2.00	June 9, 2003	<p>Continue with updates to merge Release 2 changes into the document. Changes in this revision include:</p> <ul style="list-style-type: none"> • Correct the target GPR (from rd to rt) in the SLTI and SLTIU instructions. This appears to be a day-one bug. • Correct CPR number, and missing data movement in the pseudocode for the MTC0 instruction. • Add note to indicate that the CACHE instruction does not take Address Error Exceptions due to mis-aligned effective addresses. • Update SRL, ROTR, SRLV, ROTRV, DSRL, DROTR, DSRLV, DROTRV, DSRL32, and DROTR32 instructions to reflect a 1-bit, rather than a 4-bit decode of shift vs. rotate function. • Add programming note to the PrepareForStore PREF hint to indicate that it cannot be used alone to create a bzero-like operation. • Add note to the PREF and PREFX instruction indicating that they may cause Bus Error and Cache Error exceptions, although this is typically limited to systems with high-reliability requirements. • Update the SYNCI instruction to indicate that it should not modify the state of a locked cache line. • Establish specific rules for when multiple TLB matches can be reported (on writes only). This makes software handling easier.
2.50	July 1, 2005	<p>Changes in this revision:</p> <ul style="list-style-type: none"> • Correct figure label in LWR instruction (it was incorrectly specified as LWL). • Update all files to FrameMaker 7.1. • Include support for implementation-dependent hardware registers via RDHWR. • Indicate that it is implementation-dependent whether prefetch instructions cause EJTAG data breakpoint exceptions on an address match, and suggest that the preferred implementation is not to cause an exception. • Correct the MIPS32 pseudocode for the LDC1, LDXC1, LUXC1, SDC1, SDXC1, and SUXC1 instructions to reflect the Release 2 ability to have a 64-bit FPU on a 32-bit CPU. The correction simplifies the code by using the ValueFPR and StoreFPR functions, which correctly implement the Release 2 access to the FPRs. • Add an explicit recommendation that all cache operations that require an index be done by converting the index to a kseg0 address before performing the cache operation. • Expand on restrictions on the PREF instruction in cases where the effective address has an uncached coherency attribute. •

Revision History

Revision	Date	Description
2.60	June 25, 2008	<ul style="list-style-type: none"> Changes in this revision: • Applied the new B0.01 template. • Update RDHWR description with the UserLocal register. • added PAUSE instruction • Ordering SYNCs • CMP behavior of CACHE, PREF*, SYNCI • CVT.S.PL, CVT.S.PU are non-arithmetic (no exceptions) • *MADD.fmt & *MSUB.fmt are non-fused. • various typos fixed
2.61	July 10, 2008	<ul style="list-style-type: none"> • Revision History file was incorrectly copied from Volume III. • Removed index conditional text from PAUSE instruction description. • SYNC instruction - added additional format “SYNC stype”
2.62	January 2, 2009	<ul style="list-style-type: none"> • LWC1, LWXC1 - added statement that upper word in 64bit registers are UNDEFINED. • CVT.S.PL and CVT.S.PU descriptions were still incorrectly listing IEEE exceptions. • Typo in CFC1 Description. • CCRes is accessed through \$3 for RDHWR, not \$4.
3.00	March 25, 2010	<ul style="list-style-type: none"> • JALX instruction description added. • Sub-setting rules updated for JALX. •
3.01	June 01, 2010	<ul style="list-style-type: none"> • Copyright page updated. • User mode instructions not allowed to produce UNDEFINED results, only UNPREDICTABLE results.
3.02	March 21, 2011	<ul style="list-style-type: none"> • RECIP, RSQRT instructions do not require 64-bit FPU. • MADD/MSUB/NMADD/NMSUB pseudo-code was incorrect for PS format check.
3.50	September 20, 2012	<ul style="list-style-type: none"> • Added EVA load/store instructions: LBE, LBUE, LHE, LHUE, LWE, SBE, SHE, SWE, CACHEE, PREFE, LLE, SCE, LWLE, LWRE, SWLE, SWRE. • TLBWI - can be used to invalidate the VPN2 field of a TLB entry. • FCSR.MAC2008 bit affects intermediate rounding in MADD.fmt, MSUB.fmt, NMADD.fmt and NMSUB.fmt. • FCSR.ABS2008 bit defines whether ABS.fmt and NEG.fmt are arithmetic or not (how they deal with QNAN inputs).
3.51	October 20, 2012	<ul style="list-style-type: none"> • CACHE and SYNCI ignore RI and XI exceptions. • CVT, CEIL, FLOOR, ROUND, TRUNC to integer can't generate FP-Overflow exception.
5.00	December 14, 2012	<ul style="list-style-type: none"> • R5 changes: DSP and MT ASEs -> Modules • NMADD.fmt, NMSUB.fmt - for IEEE2008 negate portion is arithmetic.
5.01	December 15, 2012	<ul style="list-style-type: none"> • No technical content changes: • Update logos on Cover. • Update copyright page.

Revision	Date	Description
5.02	April 22, 2013	<ul style="list-style-type: none"> Fix: Figure 2.26 Are64BitFPOperationsEnabled Pseudocode Function - “Enabled” was missing. R5 change retroactive to R3: removed FCSR.MCA2008 bit: no architectural support for fused multiply add with no intermediate rounding. Applies to MADD.fmt, MSUB.fmt, NMADD.fmt, NMSUB.fmt. Clarification: references to “16 FP registers mode” changed to “the FR=0 32-bit register model”; specifically, paired single (PS) instructions and long (L) format instructions have UNPREDICTABLE results if FR=0, as well as LUXC1 and SUXC1. Clarification: C.cond.fmt instruction page: cond bits 2..1 specify the comparison, cond bit 0 specifies ordered versus unordered, while cond bit 3 specifies signaling versus non-signaling. R5 change: UFR (User mode FR change): CFC1, CTC1 changes.
5.03	August 21, 2013	<ul style="list-style-type: none"> Resolved inconsistencies with regards to the availability of instructions in MIPS32r2: MADD.fmt family (MADD.S, MADD.D, NMADD.S, NMADD.D, MSUB.S, MSUB.D, NMSUB.S, NMSUB.D), RECIP.fmt family (RECIP.S, RECIP.D, RSQRT.S, RSQRT.D), and indexed FP loads and stores (LWXC1, LDXC1, SWXC1, SDXC1). The appendix section A.2 “Instruction Bit Encoding Tables”, shared between Volume I and Volume II of the ARM, was updated, in particular the new upright delta Δ mark is added to Table A.2 “Symbols Used in the Instruction Encoding Tables”, replacing the inverse delta marking ∇ for these instructions. Similar updates made to microMIPS’s corresponding sections. Instruction set descriptions and pseudocode in Volume II, Basic Instruction Set Architecture, updated. These instructions are required in MIPS32r2 if an FPU is implemented. . Misaligned memory access support for MSA: see Volume II, Appendix B “Misaligned Memory Accesses”. Has2008 is required as of release 5 - Table 5.4, “FIR Register Descriptions”. ABS2008 and NAN2008 fields of Table 5.7 “FCSR RegisterField Descriptions” were optional in release 3 and could be R/W, but as of release 5 are required, read-only, and preset by hardware. FPU FCSR.FS Flush Subnormals / Flush to Zero behavior is made consistent with MSA behavior, in MSACSR.FS: Table 5.7, “FCSR Register Field Descriptions”, updated. New section 5.8.1.4 “Alternate Flush to Zero Underflow Handling”. Volume I, Section 2.2 “Compliance and Subsetting” noted that the L format is required in MIPS FPUs, to be consistent with Table 5.4 “FIR Register Field Definitions” . Noted that UFR and UNFR can only be written with the value 0 from GPR[0]. See section 5.6.5 “User accessible FPU Register model control (UFR, CP1 Control Register 1)” and section 5.6.5 “User accessible Negated FPU Register model control (UNFR, CP1 Control Register 4)”
5.04	December 11, 2013	<p>LLSC Related Changes</p> <ul style="list-style-type: none"> Added ERETNC. New. Modified SC handling: refined, added, and elaborated cases where SC can fail or was UNPREDICTABLE. <p>XPA Related Changes</p> <ul style="list-style-type: none"> Added MTHC0, MFHC0 to access extensions. All new. Modified MTC0 for MIPS32 to zero out the extended bits which are writable. This is to support compatibility of XPA hardware with non XPA software. In pseudo-code, added registers that are impacted. MTHC0 and MFHC0 - Added RI conditions.

Revision History

Revision	Date	Description
6.00 - R6U draft	Dec. 19, 2013	<ul style="list-style-type: none"> Feature complete R6U draft of Volume II new instructions.
	Jan 14-16, 2014	<ul style="list-style-type: none"> Split MAX.fmt-family, instruction description that described multiple instructions, into separate instruction description pages MAX.fmt, MAX_A.fmt, MIN.fmt, MIN_A.fmt. Mnemonic change: AUIPA changed to ALUIPC, Aligned Add Upper Immediate to PC. Now all Release 6 new PC relative instructions end in “p”. Renamed CMP.cond.fmt -> CMP.condn.fmt, i.e. renamed 5-bit cond field “condn” to distinguish it from old 4-bit cond field. Cleaning up descriptions of NAL and BAL to reduce confusion about deprecation versus removal of BLTZAL and BGEZAL. DAHI and DATI use <i>rs src/dest</i> register, not <i>rt</i>. Table showing that the compact branches are complete, reversing <i>rs</i> and <i>rt</i> for BLEC, BGTC, BLEUC, BGTUC Forbidden slot RI required; takes exception like delay slot; boilerplate consistency automated. MOD instruction family: remainder has same sign as dividend Updated to R6U 1.03
	Jan 17, 2014	<ul style="list-style-type: none"> NAL, BAL: improved confusing explanation of how NAL and BAL used to be special cases of BLEZAL, etc., instructions removed by Release 6 Forbidden Slot boilerplate: requires Reserved Instruction exception for control instructions, even if interrupted: exception state (EPC, etc.) points to branch, not Forbidden Slot, like delay slot.
	Jan 20, 2014	<ul style="list-style-type: none"> Fixed bugs and changed instruction encodings: BEQZALC, BNEZALC, BGEUC, BLTUC, BLEZLC family, BC1EQZ, BC2EQZ, BC1NEZ, BC2NEZ, BITSWAP AUI, BAL
R6U draft	Feb 10, 2014	<ul style="list-style-type: none"> Refactored “Compatibility and Subsetting” sections of Volumes I and II for reuse without replication. Updated Volume II tables of instructions by categories (preceding section entitled Alphabetical List of Instructions) for R6U changes.
R6U-pre-release draft	Feb. 11, 2014	Technical Publications preparing for release.

Summary of all R6U drafts up to this date - R6U version 1.03

- MIPS3D removed from the Release 6 architecture.
- Some 3-source instructions (conditional moves) replaced with new 2-source instructions: MOVZ/MOVN.fmt replaced by SELEQZ/SELNEZ.fmt; MOVZ/MOVN replaced by SELEQZ/SELNEZ.
- PREF/PREFE: Unsound prefetch hints downgraded; optional implementation dependent prefetch hints expanded.

Free up Opcode Space

- Change encodings of LL/SC/LLD/SCD/PREF/CACHE, reducing offset from 16 bits to 9 bits
- SPECIAL2 encodings changed: CLO/CLZ/DCLO/DCLZ
- Other changes mentioned below: traps with immediate operands removed (ADDI/DADDI, TGEI/TGEIU/TLTI/TLTIU/TEQI/TNEI)
- Free 15 major opcodes: COP1X, SPECIAL2, LWL/LWR, SWL/SWR, LDL/LDR, SDL/SDR, LL/SC, LLD/SCD, PREF, CACHE, as described below, by changing encodings.

Revision	Date	Description
		<p><u>Integer Multiply and Divide</u></p> <ul style="list-style-type: none"> Integer accumulators (HI/LO) removed from base Release 6, moved to DSPr6, allowed only with microMIPS: MFHI, MTHIO, MFLO, MTLO, MADD, MADDU, MUL, MSUB, MSUBU removed. Release 6 adds multiply and divide instructions that write to same-width register: MULT replaced by MUL/MUH; MULTU replaced by MULU/MUHU; DIV replaced by DIV/MOD; DIVU replaced by DIVU/MODU; similarly for 64-bit DMUH, etc. <p><u>Control Transfer Instructions (CTIs)</u></p> <ul style="list-style-type: none"> Branch likely instructions removed by Release 6: BEQL, etc. Enhanced compact branches and jumps provided No delay slots; back-to-back branches disallowed (forbidden slot) More complete set of conditions: BEQC/BNEC, all signed and unsigned reg-reg comparisons, e.g. BLTC, BLTUC; all comparisons against zero, e.g. BLTZC More complete set of conditional procedure call instructions: BEQZALC, BNEZALC Large offset PC-relative branches: BC/BALC 26-bit offset (scaled by 4); BEQZC/BNEZC 21-bit offset JIC/JIALC: “indexed” jumps, jump to register + sign extended 16-bit offset Trap-in-overflow adds with immediate removed by MIOPSR6: ADDI, DADDI; replaced by branches on overflow BOVC/BNVC. Redundant JR.HB removed, aliased to JALR.HB with rdest=0. BLTZAL/BGEZAL removed; not used because unconditionally wrote link register <p>SSNOP identical to NOP.</p> <p><u>Misaligned Memory Accesses</u></p> <ul style="list-style-type: none"> Unaligned load/store instructions (LWL/LWR, etc.) removed from Release 6. Support for misaligned memory accesses must be provided by a Release 6 system for all ordinary loads and stores, by hardware or by software trap-and-emulate. CPU scalar ALIGN instruction <p><u>Address Generation and Constant Building</u></p> <ul style="list-style-type: none"> Instructions to build large constants (such as address constants): AUI (Add upper immediate), DAHI, DATI. Instructions for PC-relative address formation: ADDIUPC, ALUIPC. PC-relative loads: LWP, LWUP, LDP. Indexed FPU memory accesses removed: LWXC1, LUXC1, PFX, etc. Load-scaled-address instructions: LSA, DLSA 32-bit address wrapping improved. <p><u>DSP ASE</u></p> <ul style="list-style-type: none"> DSP ASE and SmartMIPS disallowed; recommend MSA instead DSPr6 to be defined, used with microMIPS. Instructions promoted from DSP ASE to Base ISA: BALIGN becomes Release 6 ALIGN, BITREV becomes Release 6 BITSWAP

Revision	Date	Description
		<p><u>FPU and co-processor</u></p> <ul style="list-style-type: none"> • Instruction encodings changed: COP2 loads/stores, cache/prefetch, SPECIAL2: LWC2/SWC2, LDC2/SWC2 • FR=0 not allowed, FR=1 required. • Compatibility and Subsetting section amended to allow a single precision only FPU (FIR.S=FIR.W=1, FIR.D=FIR.L=0.) • Paired Single (PS) removed from the Release 6 architecture, including: COP1.PS, COP1X.PS, BC1ANY2, BC1ANY4, CVT.PS.S, CVT.PS.W. • FPU scalar counterparts to MSA instructions: RINT.fmt, CLASS.fmt, MAX/MAXA/MIN/MINA.fmt. • Unfused multiply adds removed: MADD/MSUB/NMADD/NMSUB.fmt • IEEE2008 Fused multiply adds added: MADDF/MSUBF.fmt • Floating point condition codes and related instructions removed: C.cond.fmt removed, BC1T/BC1F, MOVF/MOVT. • MOVF/MOVT.fmt replaced by SEL.fmt • New FP compare instruction CMP.cond.fmt places result in FPR and related BC1EQZ/BC2EQZ • New FP comparisons: CMP.cond.fmt with cond = OR (ordered), UNE (Unordered or Not Equal), NE (Not Equal). • Coprocessor 2 condition codes removed: BC2F/BC2T removed, replaced by BC2NEQZ/BC2EQZ <p><u>Recent R6U architecture changes not fully reflected in this draft:</u></p> <ul style="list-style-type: none"> • This draft does not completely reflect the new 32-bit address wrapping proposal but still refers in some places to the old IAM (Implicit Address Mode) proposal. • This draft does not yet reflect constraints on endianness, in particular in the section on Misaligned memory access support: e.g. code and data must have the same endianness, Status.RE is removed, etc. • BC1EQZ/BC1NEZ will test only bit 0 of the condition register, not all bits. • This draft does not yet say that writing to a 32-bit FPR renders upper bits of a 64 bit FPR or 128 bit floating point register UNPREDICTABLE; it describes the old proposal of zeroing the upper bits. <p><u>Known issues:</u></p> <ul style="list-style-type: none"> • This draft describes Release 6, as well as earlier releases of the MIPS architecture. E.g. instructions that were present in MIPSr5 but which were removed in Release 6 are still in the manual, although they should be clearly marked “removed by Release 6” to indicate that they have been removed by Release 6. • R6U new instruction pseudocode is 64-bit, rather than 32-bit, albeit attempting to use notations that apply to both. • Certain new instruction descriptions are “unsplit”, describing families of instructions such as all compact branches, rather than separate descriptions of each instruction. This facilitates comparison and consistency, but currently allows certain MIPS64 Release 6 instructions to appear inappropriately in the MIPS32 Release 6 manual. A future release of the manual will “split” these instruction family descriptions, e.g. the compact branch family will be split up into at least 12 different instruction descriptions. • R6U requires misalignment support for all ordinary memory reference instructions, but the pseudocode does not yet reflect this. Boilerplate has been added to all existing instructions saying this. • The new R6U PC-relative loads (LWP, LWUP, LDP) in this draft incorrectly say that misaligned accesses are permitted.

Revision	Date	Description
R6U-pre-release draft	Feb. 13, 2014	<ul style="list-style-type: none"> ALIGN/DALIGN: clarified bp=0 behavior ALIGN/DALIGN pseudocode used as logical OR rather than MIPS' pseudocode concatenate. Removed incorrect note about not using r31 as a source register to BAL. Release 6 requires BC1EQZ/BC1NEZ if an FPU is present, i.e. they cannot signal RI. R6U 1.05 change: BC1EQZ/BC1NEZ test only bit 0 of the FPY; changed from testing if any bit nonzero; helps with trap-and-emulate of DP on an SP-only FPU. Known problem: R6U 1.05 change not yet made: all 32-bit FP operations leave upper bits of 64 bit FOR and/or 128-bit MSR unpredictable; helps with trap-and-emulate of DP on an SP-only FPU. Clearly marked all .PS instructions as removed via removed by Release 6 in instruction format. DMUL, DMULTU, DDIV, DDIVU marked removed by Release 6 Started using =Release 6 notation to indicate that an instruction has been changed but is still present. JR.HB =Release 6, aliased to JALR.HB. SSNOP =Release 6, treated as NOP. Noted that BLTZAL and BGEZAL are removed by Release 6, the special cases NAL=BLTZAL with rs=0 and BAL=BGEZAL with rs=0, remain supported by Release 6. Marked conditional traps with immediate removed by Release 6. Overeager propagation of r31 restriction to non-call instructions⁵ removed. Emphasized that unconditional compact CTIs have neither Delay Slot nor Forbidden Slot. SDBBP updated for R6P facility to disable if no hardware debug trap handler UFR/UNFR (User-mode FR facility) disallowed in Release 6: changes to CTC1 and CFC1 instructions.
R6U ARM Volume II	February 14, 2014	<ul style="list-style-type: none"> Last minute change: BC1EQZ.fmt and BC1NEZ.fmt test only bit 0, least significant bit, of FPR.
6.00 preliminary release		Known issues:
		<ul style="list-style-type: none"> Similar changes to SEL.fmt, SELEQZ.fmt, SELNEZ.fmt not yet made.
post-6.00	February 20, 2014	<ul style="list-style-type: none"> FPU truth consuming instructions (BC1EQZ.fmt, BC1NEZ.fmt, SEL.fmt, SELEQZ.fmt, SELNEZ.fmt) change completed: test bit 0, least-significant-bit, of FPR containing condition.
6.01	December 1, 2014	<ul style="list-style-type: none"> Production Release. Add DVP and EVP instructions for multithreading. Add POP and SOP encoding nomenclature to opcode tables in appendix A
6.02	December 10, 2014	<ul style="list-style-type: none"> JIC format changed from JIC offset(rt) to JIC rt, offset. JIALC format changed from JIALC offset(rt) to JIALC rt, offset. 'offset' removed from NAL format.
